	J. Net sparker.....	49-51
	K. OWASP zap.....	52-53

4. Identified vulnerabilities.....	54
A. Domain: MalwareBytes.com.....	54-55
1. Security misconfiguration.....	56
i. HTTP strict transport security errors and warnings.....	56
• Impacts of HSTS errors and warnings.....	56
• Step to reproduce this vulnerability.....	57
• Proof of concept.....	57-59
• Proof of existence of vulnerability.....	60-61
• Solutions to the vulnerability (Remedy)	61
2. Sensitive data exposure.....	62
i. Weak ciphers enabled.....	62
• Impacts of Weak ciphers.....	62
• Step to reproduce this vulnerability.....	63
• Proof of concept.....	64-70
• Proof of existence of vulnerability.....	70
• Solutions to the vulnerability (Remedy)	71
3. Using components with known vulnerabilities.....	72
i. Possible BREACH attack detected.	72
• Impacts of BRECH attack.....	72
• Step to reproduce this vulnerability.....	73
• Proof of concept.....	73-75
• Proof of existence of vulnerability.....	75-76
• Solutions to the vulnerability (Remedy)	77
ii. Outdated version of bootstrap. Possible XSS attack	78
• Impacts of outdated bootstrap.....	78-79
• Step to reproduce this vulnerability.....	79
• Proof of concept.....	79-81
• Proof of existence of vulnerability.....	82
• Solutions to the vulnerability (Remedy)	83
B. Domain: Inmobi.com.....	84-86
1. Sensitive data exposure.....	87
i. Session cookie not marked as secure possible MIMT attack	87
• Impacts of Session cookie not marked as secure.....	87
• Step to reproduce this vulnerability.....	88
• Proof of concept.....	89-90
• Proof of existence of vulnerability.....	91-92

• Solutions to the vulnerability (Remedy)	93
ii. Source code disclosure PHP.....	94
• Impacts of source code disclosure.....	94
• Step to reproduce this vulnerability.....	95
• Proof of concept.....	95-96
• Proof of existence of vulnerability.....	97-100
• Solutions to the vulnerability (Remedy)	100
2. Using components with known vulnerabilities.....	101
i. Outdated JQuery version possible XSS attack detected.	101
• Impacts of outdated jquery.....	101-102
• Step to reproduce this vulnerability.....	102
• Proof of existence of vulnerability.....	103-104
• Solutions to the vulnerability (Remedy)	104
C. Domain: Merck.com.....	105-106
1. Using components with known vulnerabilities.....	107
i. Outdated Word press software possible SSRF attack	107
• Impacts of outdated word press.....	107-108
• Step to reproduce this vulnerability.....	108
• Proof of existence of vulnerability.....	109
• Solutions to the vulnerability (Remedy)	109
D. Domain: curl.com.....	110-111
1. Using components with known vulnerabilities.....	112
i. Outdated version of PHP.	112
• Impacts of outdated version of PHP.....	112-114
• Step to reproduce this vulnerability.....	114
• Proof of existence of vulnerability.....	115
• Solutions to the vulnerability (Remedy)	116
2. Sensitive data exposure.....	117
i. RSA private key compromised.	117
• Impacts of RSA private key compromised.....	117
• Step to reproduce this vulnerability.....	118
• Proof of concept.....	118-120
• Proof of existence of vulnerability.....	120-122
• Solutions to the vulnerability (Remedy)	122

Introduction.

Welcome to my bug bounty journal, where I document my exciting journey into the realm of bug bounty programs. Bug bounty programs offer a unique opportunity for ethical hackers like me to contribute to the security of various organizations by identifying and reporting vulnerabilities in their systems and applications.

In this journal, I will cover various aspects of my bug bounty journey. Firstly, I introduce the bug bounty methodology, outlining the systematic approach I followed in identifying, exploiting, and reporting vulnerabilities. This methodology served as the foundation for my efforts and ensured a structured and efficient approach to my bug bounty endeavors.

I then delve into the different phases I encountered during my bug bounty activities. From reconnaissance and vulnerability discovery to exploitation and reporting, each phase played a crucial role in my journey. I discuss the strategies and techniques employed in each phase, maximizing my chances of success.

To aid my bug bounty activities, I utilized a range of tools. These tools, including reconnaissance and information gathering tools, vulnerability scanners, and exploit frameworks, streamlined my workflow and helped me uncover potential security flaws effectively. I provide insights into the tools used and their impact on my bug bounty experience.

Throughout my bug bounty engagements, I explored various vulnerabilities. I detail these vulnerabilities, discussing their impact, exploitability, and potential consequences. I provide insights into the specific systems or applications affected, along with the steps taken to reproduce and validate these vulnerabilities.

Then I outline the obstacles I encountered during my bug bounty journey and share how I overcame them. I provide strategies, workarounds, and lessons learned from each challenge, showcasing my problem-solving abilities. Lastly, I reflect upon the overall experience gained from my bug bounty activities and share the key takeaways from my journey. I discuss the valuable insights acquired, the skills developed, and the personal growth experienced because of participating in bug bounty programs.

By documenting my bug bounty experiences and sharing them in this journal, I aim to inspire fellow cybersecurity enthusiasts, contribute to the bug bounty community, and continue my own growth as a proficient ethical hacker.

1. Introduction to Bug bounty methodology.

I. What is a bug bounty?

Bug bounty is a process where organizations invite independent security researchers to identify and report vulnerabilities or security issues in their software systems, websites, and applications [1]. This approach allows companies to identify and address security flaws before they can be exploited by malicious actors [2].

II. Phases of bug bounty?

Bug bounty programs typically have several phases that help to ensure a systematic and thorough review of the system's security posture [3].

1. Phase 01

The first phase involves scoping, where the organization defines the target systems, applications, and vulnerabilities that are in scope for the program. This is important because it helps to focus the efforts of security researchers and ensures that the organization can adequately address any vulnerabilities that are identified [4].

2. Phase 02

The second phase involves testing, where researchers use various tools and techniques to identify vulnerabilities in the target systems and applications. This phase can include manual testing, automated scanning, and other specialized tools designed to identify specific vulnerabilities. Some of the popular tools used in bug bounty programs include **Burp Suite**, **OWASP ZAP**, **Nmap**, and **Metasploit** [5].

3. Phase 03

Once vulnerabilities are identified, the third phase involves reporting, where the researcher provides a detailed report of the vulnerability to the organization. This report should include a description of the vulnerability, its potential impact, and any recommended steps for remediation. The organization then reviews the report and validates the vulnerability [6].

4. Phase 04

The fourth and final phase is remediation, where the organization takes steps to fix the vulnerability. Depending on the nature and severity of the vulnerability, this may involve simple configuration changes or more significant changes to the software code. Once the vulnerability is remediated, the organization can then confirm the fix and close out the bug report.

Overall, bug bounty programs are an important tool for organizations to improve their security posture and stay ahead of potential threats. By working with independent security researchers, companies can identify and address vulnerabilities before they can be exploited by malicious actors, thereby reducing the risk of a security breach [7].

2. Introduction to OWASP top 10 vulnerabilities.

I. Injection.

- This is the most common attack technique that is used by intruders these days to see whether injection vulnerability is present or not in targeted system or application. Injection means attacker simply sending untrusted data to system interpreter by in using URL bar, tools, intercepting the request.
- When the attacker sends that untrusted data to the interpreter it will allow the intruders to execute harmful commands. Then attackers might be able to retrieve the data that shouldn't be visible to users.
- Some of the most used injection types are SQL injection, OS command injection and LDAP injection [8].

i. SQL injection.

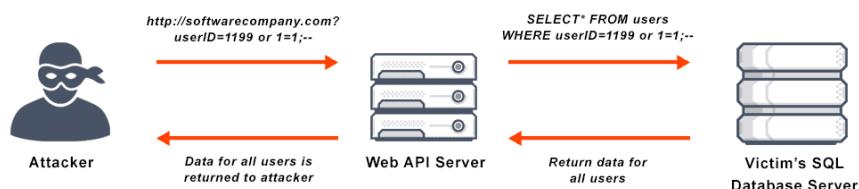

Figure 1: SQL injection example

ii. OS command injection.

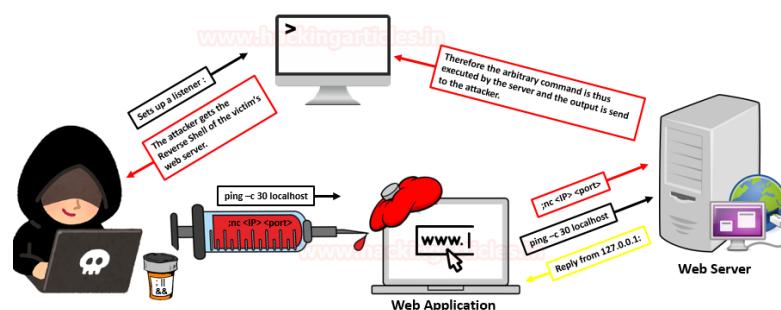

Figure 2:OS command injection

iii. LDAP injection.

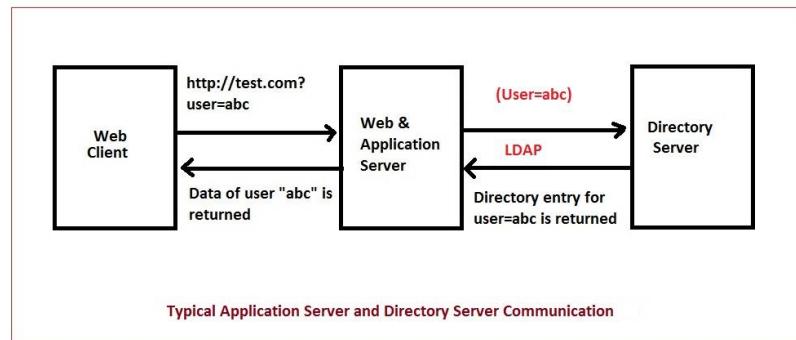

Figure 3: LDAP injection.

II. Broken Authentication.

- User authentication plays an important role in modern web applications. By this mechanism systems identify the specific user. Weakness in this system may lead to serious issues from the client perspective as well as form the system perspective.
- If a broken authentication vulnerability presents it the web application intruder may use that to impersonate user sessions, compromise session tokens or uses that to exploit other authentication flaws [9].

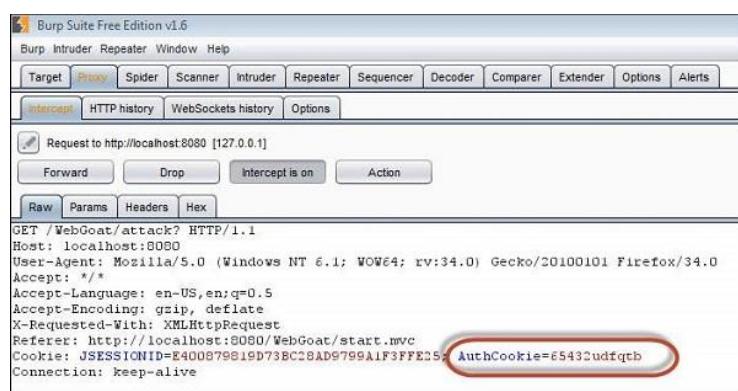

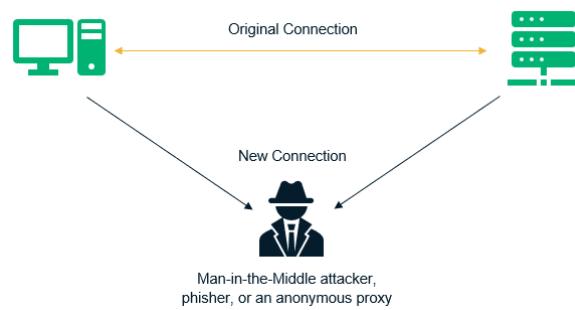

Figure 4: presence of broken authentication.

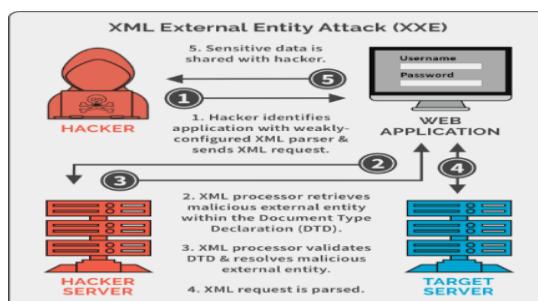

III. Sensitive Data Exposure.

- Web applications may not fully protect the data transmitting over the network or when storing sensitive information. Attacker will use that vulnerability to intercept the network and gather the sensitive information, modify that information, or steal that information and use it to exploit other system vulnerabilities.
- For example, if intruder able to get sensitive data he/she may be able to log in to the system by stealing authenticated user credentials, if he can log in as administrator attacker can modify the system configurations and he can disable security features to gain the full control of the web application [10].

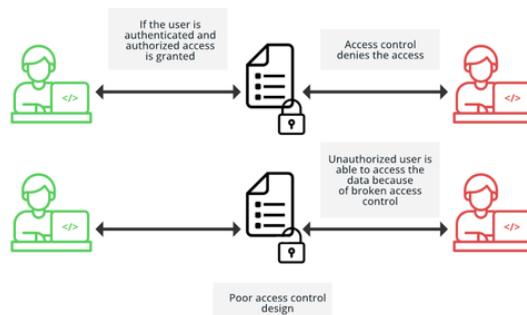

IV. XML External Entities.

- An XXE attack makes use of XML translation and data features. An attacker will be able to interact with the backend or other external systems that the application can access, as well as read files on such systems.
- Additionally, XXE assaults can activate port scanning, enable remote code execution, and denial of service attacks. They can also lead to server-side request forgery attacks and denial of service attacks. XXE assaults come in **two flavors**:
 - a. In-band XXE - The attacker receives a quick response to the XXE payload.
 - b. Blind XXE (out-of-band XXE) - When there won't be a prompt response, the attacker may want to mirror the output of his payload to a different file or his own server [11].

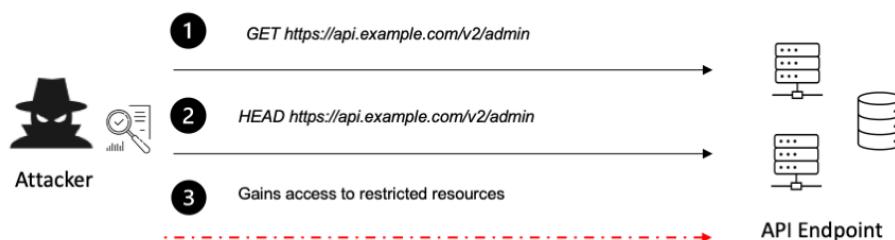

V. Broken Access Control.

- If the web application fails to enforce access controls mechanisms properly, the attacker can use that as an entry point to do various harmful activities in the web application. For example, there are web pages that are hidden from the normal user. Those may only be available to authorized persons [12].
- If this vulnerability is present normal users also be able to view that hidden web pages without proper authorization. This kind of attacks may lead,
 - a. Disclosure of sensitive information.
 - b. Gain access to unauthorized functionality.

VI. Security Misconfiguration.

- Security misconfigurations mean when the developer of the application may not properly implement the security measures to address all the possible attacks. That may lead to big problems like gaining unauthorized access to the system or database, stealing tokens and sessions [13].
- There are some most common security misconfigurations,
 - a. Permission on cloud services is poorly configured such as S3 bucket.
 - b. Unnecessary features are enabled such as services, pages, accounts, and privileges.
 - c. HTTP security headers are not used or too much information is revealed in the server HTTP header.

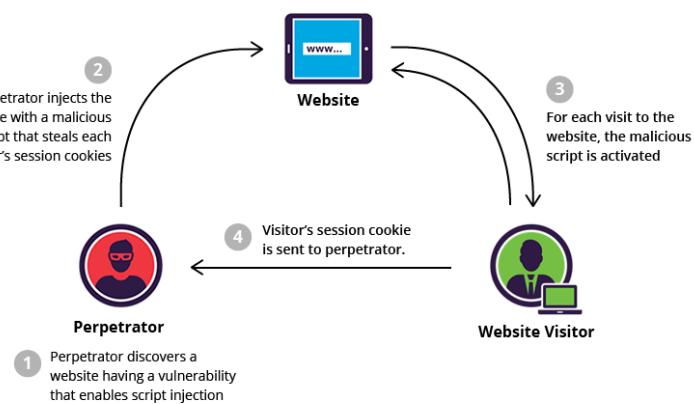

VII. Cross-Site-Scripting.

- XSS is also an injection attack. In this type of attack intruder simply injecting scripts into a vulnerable application. Usually, they execute those scripts on the victim's machine. Web development languages like CSS and Java script are more likely to vulnerable to this type of attack [14].
- To be successful in this attack intruder may need to social engineering to successfully send the script to the victim. With the successful execution of the script intruder can hijack the user session. There are mainly 3 types of XSS attacks.

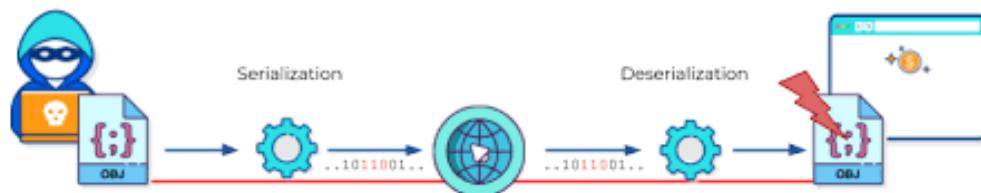

Reflected XSS - An attacker creates a malicious payload which is a portion of the victim's request to the website, and this payload is included in response back to the user by the website. A user is tricked into clicking that specific URL by the attacker to execute the payload [15].

- a. **DOM-Based XSS** - Document Object Model is a programming interface for HTML and XML, and XSS changes the document structure, style, and content.
- b. **Stored XSS** - When the user input is not sanitized and inserted into the database, stored. XSS happens. As the malicious string originates from the website's database, this is the most dangerous type of XSS attack.
- c. **Reflected XSS** - An attacker creates a malicious payload which is a portion of the victim's request to the website, and this payload is included in response back to the user by the website. A user is tricked into clicking that specific URL by the attacker to execute the payload [16].

VIII. Insecure Deserialization.

- This happens when the logic of the application is replaced by the attacker with a malicious code. It will allow intruders to perform DOS with remote code execution, privilege escalation or other attacks. To these attacks applications like e-comers web applications, forums, APIS's and application runtimes like (Tomcat, Jenkins) are vulnerable to these kinds of attacks.
- By performing this kind of attack intruder might be able to gain full control of the application. So, then they can simply steal sensitive information and other details [17].

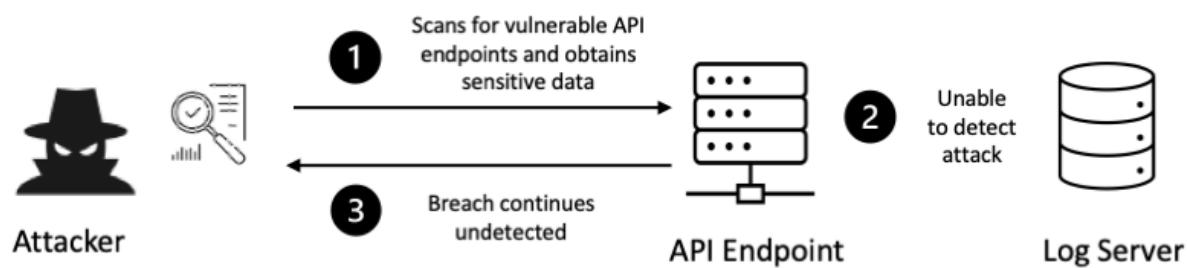

IX. Using Components with Known Vulnerabilities.

- If the underlying programs which are used on the website are outdated, there may be a high chance of finding a well-known vulnerability, which can be used to gain access to the system. So, as an attacker, one must do very simple work and that is why this vulnerability is rated low by OWASP.
- For example, let us assume that there is a website which is developed using WordPress as the content management system and the WordPress version is out-to-date, because developers have forgotten to update it.
- An attacker can easily detect the WordPress version at enumeration phase and look for a pre-defined specific vulnerability associated with that version and use it to gain access to the system. So, the attacker only must do some research on how to use the vulnerability, and it is simple as that [18].

X. Insufficient Logging and monitoring.

- This type of attack occurs when there is not enough logging and monitoring systems for the application. If so, the attacker can log in to an account that does not belong to him and can do various harmful activities on the application.
- To this problem there are some solutions like implementing intrusion detection systems, intrusion prevention systems, and logging. By implementing those system can overcome this issue on an extendable level [19].

3. Tools used in bug bounty program.

Throughout the finding vulnerabilities of web application, I have identified many web applications that had considerable amount of OWASP Top 10 vulnerabilities. I reported to the relevant party about the existence of that vulnerability on their site.

To this journal book I have used vulnerable web sites to show case the thing I learn, vulnerabilities I found, tools I used and to explain what I learn from finding those. The following vulnerable web applications are [20],

- 1. MalwareByte.com**
- 2. Inmobi.com**
- 3. Merck.com**
- 4. Curl.se**

To analyze vulnerabilities on those web applications I have used lots of techniques, theories, and various tools to figure out the vulnerability. As I mentioned before I have used lots of tools. To explain it I can categorize those tools into mainly 2 parts [21].

Note: for the ease of explanation of what kind of tools I used and how I used those tools I have only used a **1 domain** that I identified as a vulnerable web application.

- a. Reconnaissance tools. (Information gathering)**
- b. Vulnerability analysis & exploitation tools.**

Under each part there are lots of subcategories and tools that can be used to information gathering. Also, the same tool can be used to identify different types of information that we need to figure out the vulnerability.

This information will also be helpful when giving correct solutions to the identified vulnerability too.

a. Reconnaissance tools. (Information gathering)

Under the information gathering phase used many tools for different purposes. There are lots of automated tools as well as manual testing tools available. I have used some of the most recognized tools for information gathering phase under different categories.

- i. Target validation**
- ii. Subdomain Enumeration.**
- iii. Finding alive sub domains.**
- iv. Finding achieved information.**
- v. DNS Enumeration.**
- vi. Public Device Enumeration.**
- vii. Find the structure of the file system.**

Under each category I have used different types of software as well as plugins, framework's, automated bots, crawlers to gather information about the target web application.

i. Target validation.

This is the first step of vulnerability assessment. Before doing bug bounty we need to identify the vulnerable target by gathering information from all possible aspects. To target validation, I have used many inbuild and 3rd party software's.

- A. Nslookup.io**
- B. Censys**
- C. Wafw00f**
- D. Nmap**

A. Nslookup.io

From this build in Linux tool, we can identify the Ip address or the domain name system records for the given host name [22].

```
[root@error404] ~
# ping inmobi.com
PING inmobi.com (20.81.69.107) 56(84) bytes of data.
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=1 ttl=106 time=295 ms
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=2 ttl=106 time=262 ms
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=3 ttl=106 time=285 ms
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=4 ttl=106 time=290 ms
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=5 ttl=106 time=302 ms
^C
--- inmobi.com ping statistics ---
5 packets transmitted, 5 received, 0% packet loss, time 4000ms
rtt min/avg/max/mdev = 261.584/286.813/302.159/13.781 ms

[root@error404] ~
# nslookup www.inmobi.com
Server:      192.168.8.1
Address:     192.168.8.1#53

Non-authoritative answer:
www.inmobi.com canonical name = www.eastus.appgw.inmobi.com.
Name:   www.eastus.appgw.inmobi.com
Address: 20.81.69.107
```

B. Censys

Censys is a web application that has millions of hosts. We can simply type the Ip address host name in the search bar, and it will give all possible details about the host [23].

The screenshot shows the Censys search interface with the query "dns.names: \"www.inmobi.com\"". The results page displays a single host entry: 20.81.69.107, located in Virginia, United States, running Microsoft Corp-MSN-AS-BLOCK (8075) on ports 80 and 443. The left sidebar contains filters for Host Labels (Not Available), Autonomous System (1 Microsoft-Corp-MSN-AS-BLOCK), and Location (1 United States). The right sidebar includes links for Report and Docs.

C. Wafw00f (Firewall detector)

This tool can be used to identify the firewall protection for the target web application. If the web application has a firewall protection (WAF enabled) it will show the type of WAF. Otherwise, don't show the result if it doesn't have WAF protection.

WAF protection is not enabled in our testing web application [24].

The screenshot shows the Wafw00f command-line interface with the command "# wafw00f http://www.inmobi.com". The output includes a colorful ASCII art logo of a dog's head with the word "Woof!". Below the logo, it says "~ WAFW00F : v2.2.0 ~" and "The Web Application Firewall Fingerprinting Toolkit". The log concludes with "[*] Checking http://www.inmobi.com", "[+] Generic Detection results:", "[-] No WAF detected by the generic detection", and "[~] Number of requests: 7".

This site is protected by the firewall called **BIG-IP AppSec Manager (F5 Networks) WAF**.

```
[root@error404]# wafw00f http://www.paypal.com

          ( ' Woof! ')
          \   _/
        ,'
       ( ; ) = == )
      ( / ) / \ \
     \( _ ) ) / | \ \
           ) ( . |
           ) ( . |
           ) ( . |
           ) ( . |

~ WAFW00F : v2.2.0 ~
The Web Application Firewall Fingerprinting Toolkit

[*] Checking http://www.paypal.com
[+] The site http://www.paypal.com is behind BIG-IP AppSec Manager (F5 Networks) WAF.
[~] Number of requests: 2
```

D. Nmap

Nmap is a build in Linux too which can be used to identify network exploitation, host discovery and to do security auditing. It uses IP packets to identify the all the devices that are connected to the network & provide information about those devices and services that the system provides [25].

```
[root@error404]# ping inmobi.com
PING inmobi.com (20.81.69.107) 56(84) bytes of data.
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=1 ttl=106 time=283 ms
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=2 ttl=106 time=262 ms
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=3 ttl=106 time=265 ms
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=4 ttl=106 time=265 ms
64 bytes from 20.81.69.107 (20.81.69.107): icmp_seq=5 ttl=106 time=262 ms
^C
--- inmobi.com ping statistics ---
5 packets transmitted, 5 received, 0% packet loss, time 4005ms

ii. Subdomain Enumeration.

This is one of the most important parts in information gathering. In this step need to identify the sub domain that runs under the main root domain. So, by identifying those sub domains separately we can clearly go through each sub domain and can gather information's separately. To sub domain enumeration, I have used tools like,

- A. Sublist3r.
- B. Crt.sh.
- C. Google dork.
- D. Bug bounty Hunting Tool (BBHT).
- E. Recon-ng

A. Sublist3r.

```
(root@error404) [~/Sublist3r]
# python sublist3r.py

[!] Sublist3r v3.0.0 - Subdomain Enumerator
[!] By Ahmed Aboul-Ela (@aboul3la)

# Coded By Ahmed Aboul-Ela - @aboul3la

Usage: python sublist3r.py [Options] use -h for help
Error: the following arguments are required: -d/--domain

(root@error404) [~/Sublist3r]
#
```

To show the workflow of these software I have used a web application that I used to find vulnerabilities. The site called <https://www.inmobi.com/>. this web application had a high risk of attacks.

```
(root@error404) [~/Sublist3r]
# python sublist3r.py -d inmobi.com -e bing.com

[!] Sublist3r v3.0.0 - Subdomain Enumerator
[!] By Ahmed Aboul-Ela (@aboul3la)

# Coded By Ahmed Aboul-Ela - @aboul3la

[-] Enumerating subdomains now for inmobi.com
```

Up until sublis3t tools worked perfectly. From here onwards it started to give errors and not enumerating the sub domain anymore. So, this was a challenge. What I did is I skipped using this tool anymore and started to use other tools to enumerate sub domains.

B. Crt.sh

To find sub domain using this tool I used the same web applications domain and used a wild card to crawl more to find more sub domains.

C. Google dork.

This is another tool that can be used to identify sub domains of a targeted domain. Also this can be called a simple technique that can use to identify sub domains using google search engine [26].

Simply by typing **site: domain name**, can identify all the sub domains under it. We can use a crawler to filter all those sub domains for perfect sorting.

D. Bug bounty Hunting Tool (BBHT).

BBHT is a script that can be downloaded via various trusted web sites. It is an integrated tool that contains almost different types of tools that can be used in information gathering, identifying vulnerabilities, exploitation, and fixing.

It has tools like SQL map- dev, sublist3r, virtual-host-directory, wpscan, webscreenshot, lazys3, JSParser, diresearch and so many [27].

```
└─(root@error404)-[~/tools]
# ls /opt/ops/irrl/inmobi.com
asnlookup dirsearch knock    lazys3  SecLists  Sublist3r      virtual-host-discovery
crtndstry JSParser lazyrecon massdns  sqlmap-dev teh_s3_bucketeers wpscan
```

E. Recon-**ng**.

Recon-ng**** is also a well-known tool to identify sub domain of a target domain accurately. Also, it is very easy to use, and it will check sub domains in all well-known search engines.

```
[root@error404]# ./recon-ng
[*] Version check disabled.

980 www.inmobi.com
```

iii. Finding alive sub domain.

There can be thousands of sub domains under each domain. But in most case companies will change update their web application from time to time. When finding sub domain with automated tools it will go through each search engine and looks for unique sub domain that ends with ***inmobi.com**.

If the company updates their application, they might shutdown some of their sub domain as per their need. So, finding sub domain is not enough. After finding sub domain we need to gather the active sub domains. Because gathering information about inactive sub domains is not needed. Because they are no longer using sub domain anymore. To identify active sub domain, I have used a tool.

A. Htprobe.

A. Htprobe.

Htprobe is a tool that can be used to identify alive sub domains. What it simply does is it send the request to all sub domains and if a sub domain gives a reply as success of communication establishment it will count that sub domain as active sub domain.

All sub domains.

Htprobe tool identified that there are **86 sub domains** currently active from a **total of 980 sub domains**.

iv. Finding achieved information.

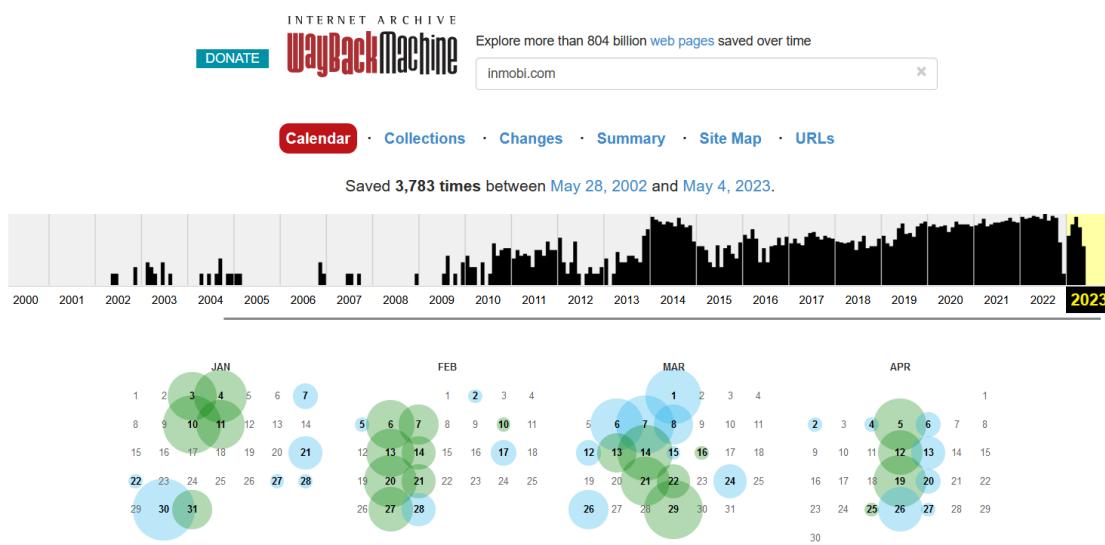

Finding older information about the application is an important part of information gathering. By finding those achieved information we can find what kind of vulnerabilities that had now what they did to fix those as so many like these.

To find those achieved information I have used an internet archive.

A. Way Back Machine.

A. Way back Machine.

This is a web tool that is simply an internet archive. It has a massive collection of snapshots of web applications, copies of its web pages, books, videos, audios, images, etc [28].

We help brands understand, identify, engage and acquire consumers.

[SEE HOW](#)

v. DNS enumeration.

In this phase what simply doing in identifying all possible DNS servers and their matching entries of the targeted organization or web application. By doing this we can reveal the size of the target application and can measure the size of the attack surface easily. To do this enumeration I have used many tools.

- A. Dnsrecon**
- B. DNSEnum**
- C. Host Command**

A. Dnsrecon.

Dnsrecon is a powerful tool that cam as a build in tool in kali Linux. By using this tool we can reverse look up an IP range, domain brute force enumeration, cache snooping against name servers, standard records enumeration, etc.

```
[root@error404] ~

vi. Public Device Enumeration.

The purpose of this step is to identify all devices that are attached to the system or web application. To this step, I have used one tool. From this tool it will give all connected devices information in the targeted domain.

A. Shodan.io

A. Shodan.io

By this tool if there are any public IP addresses exposing a server on a certain port it will be available on this web site. It also shows details about web servers, banners, ISP, SSH, and FTP [29].

vii. Finding structure of the file system.

By using these tools, we can identify the structure of the file system. This is a very important step to take in the information gathering phase before moving into vulnerability scanning in the target domain. I have used many tools in this step-in order to find the correct structure of the file system.

- A. Dirsearch.**
- B. Dirb Tool.**
- C. OWASP dirbuster.**

A. Diresearch.

This is also a very famous tool that is used to brute force directories and files on websites. I have used this tool to find hidden files of web application, this tool will find those hidden files and directories on a web server by sending HTTP requests to the server and then analyze the response.

```
[root@error404] ~/tools/dirsearch
# ./dirsearch.py -u https://inmobi.com -e html,php,jsp,json
[!] [!] [!] v0.4.3

Extensions: html, php, jsp, json | HTTP method: GET | Threads: 25 | Wordlist size: 11152
Output: /root/tools/dirsearch/reports/https_inmobi.com/_23-05-14_20-31-26.txt
Target: https://inmobi.com/
[20:31:26] Starting:
[          ] 4%    538/11152      51/s      job:1/1 errors:0
```

```
[root@error404] ~/tools/dirsearch
# ./dirsearch.py -u https://inmobi.com -e html,php,jsp,json
[!] [!] [!] v0.4.3

Extensions: html, php, jsp, json | HTTP method: GET | Threads: 25 | Wordlist size: 11152
Output: /root/tools/dirsearch/reports/https_inmobi.com/_23-05-14_20-31-26.txt
Target: https://inmobi.com/
[20:31:26] Starting:
Task Completed
```

B. Dirb Tool.

A Dirb tool is a tool that can be used to identify the web contents of specific web sites. It will look for hidden or existing web objects of the web application. Dirb will identify those web content by launching directory attack against a web server and analyzing the requests and its response. Using this tool, we can simply identify all the contents that are available in the target domain.

```

C. OWASP dirbuster.

OWASP dirbuster is another well known Linux built in tool that can be used to brute force directories and file names on the web application servers. Dirbuster comes with total of 9 different lists, this makes dirbuster extremely effective at finding those hidden files and directories of target domain.

b. Vulnerability analyzing tools.

Under the vulnerability phase many tools are used to identify vulnerabilities and confirm its existence using various automated tools as well as using frameworks. There are lots of automated tools as well as manual testing tools available. I have used some of the most recognized tools for vulnerability gathering phase. For the vulnerability analysis I have used automated tools as well as manual testing tools for the confirmation of existence of vulnerabilities.

- A. SSLyze.**
- B. Commix.**
- C. Crlf.**
- D. Corsy.**
- E. XSSStrike.**
- F. Httpsmuggler.**
- G. Oralyzer.**
- H. Burp suite.**
- I. Nikto scan.**
- J. Net sparker.**
- K. OWASP zap.**

A. SSLyze.

SSLyze is a tool which can be used to enumerate the SSL/TLS configuration of a particular server after connecting to it. Various issues such as bad certificates, weak cipher suites, Heartbleed, ROBOT can be identified with SSLyze very easily.

B. Commix.

As there is an underlying operating system which hosts the target website, we may able to run OS commands related to that OS through the web application. Commix is a tool which can be used to identify potential OS command injection vulnerabilities. Commix scan for our target can be performed as follows.

```
[root@error404:~]# commix --url http://inmobi.com

```

D. Corsy.

some HTTP headers that define trusted web origins and associated properties are used by the CORS protocol to allow access from other resources of the website such as subdomains and trusted third parties. Sensitive information may be disclosed to attackers by exploiting vulnerabilities related to CORS. Corsy is a python tool which can be used to detect CORS misconfigurations.

```
(root@error404:[~/Corsy]
# python3 corsy.py -u https://inmobi.com

C O R S Y  {v1.0-beta}

- No misconfigurations found.
```

E. XSStrike.

This tool can be sued to identify the XSS vulnerability's if presents on the target web application. There are many types of XSS attacks. All these attack types can be tested using the python tool called XSStrike,

```
(root@error404:[~/XSStrike]
# python3 xsstrike.py -u "http://inmobi.com" --crawl

XSStrike v3.1.5

H. Burp suite.

Burp Suite is a popular integrated platform for performing web application security testing. Burp Suite provides a range of tools and features to help security professionals and penetration testers identify and exploit security vulnerabilities in web applications. Some of the key features of Burp Suite include:

- A web proxy that allows users to intercept and modify web traffic in real-time.
- A web vulnerability scanner that automatically identifies security vulnerabilities in web applications.
- An application-aware spider that can discover hidden content and functionality in web applications.
- A repeater tool that allows users to modify and re-send requests to web applications.
- A sequencer tool that can test the randomness and strength of tokens and session identifiers.
- A collaborator tool that can be used to identify blind vulnerabilities in web applications.

I. Nikto scan.

Nikto is an open-source web server scanner that is used to identify potential security vulnerabilities in web servers and applications. It is a command-line tool that can be used to scan web servers for common vulnerabilities and misconfigurations, including outdated software, insecure file permissions, and known exploits.

- Support for multiple protocols, including HTTP and HTTPS.
- Integration with other security tools and services, including the National Vulnerability Database (NVD) and the Common Vulnerability Scoring System (CVSS).
- Customizable scanning options that allow users to tailor their scans to specific systems or software configurations.
- Automated scanning capabilities that reduce the need for manual intervention and make it easy to scan large and complex web servers.

J. Netsparker.

Netsparker is a powerful web application security scanner that is used to identify and report security vulnerabilities in web applications. It is designed to be highly automated and easy to use, making it an ideal tool for security professionals, web developers, and system administrators.

- Automated scanning capabilities that reduce the need for manual intervention and make it easy to scan large and complex web applications.
- Customizable scanning options that allow users to tailor their scans to specific systems or software configurations.
- Integration with other security tools and services, including the OWASP Top 10 list of web application vulnerabilities.

URL: <https://www.tide.co/>

List of Supported Weak Ciphers:

- TLS_RSA_WITH_AES_128_CBC_SHA (0x002F)
- TLS_RSA_WITH_AES_256_CBC_SHA (0x0035)
- TLS_RSA_WITH_AES_128_CBC_SHA256 (0x003C)
- TLS_RSA_WITH_AES_256_CBC_SHA256 (0x003D)
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA (0x0023)
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA (0x0014)
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 (0x0027)
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA256 (0x0028)

Vulnerability Details

Netsparker detected that weak ciphers are enabled during secure communication (SSL).

You should allow only strong ciphers on your web server to protect secure communication with your visitors.

Impact

Attackers might decrypt SSL traffic between your server and your visitors.

Actions to Take

For Apache, you should modify the SSLCipherSuite directive in the httpd.conf file.

K. OWASP ZAP

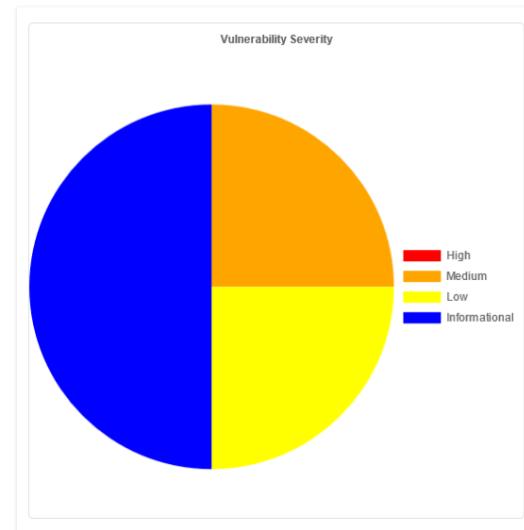

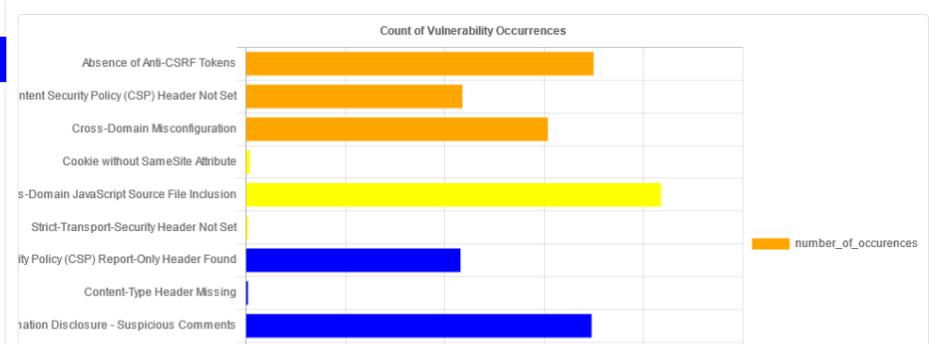

OWASP ZAP (Zed Attack Proxy) is a free and open-source web application security scanner that is designed to help security professionals and system administrators identify and address security vulnerabilities in web applications. It is a powerful tool that can be used to perform comprehensive security assessments of web applications, including identifying vulnerabilities such as cross-site scripting (XSS), SQL injection, and other types of security flaws.

- Support for a wide range of web application technologies, including HTML5, Ajax, and REST.
- Built-in proxy functionality that allows for easy interception and modification of web traffic.
- An intuitive user interface that makes it easy to configure and manage scans.
- Integration with other security tools and services, including the National Vulnerability Database (NVD) and the Common Vulnerability Scoring System (CVSS).
- Customizable reporting capabilities, including the ability to generate detailed reports in various formats, such as HTML, CSV, and JSON.

The screenshot shows the OWASP ZAP interface. The top menu bar includes File, Edit, View, Analyse, Report, Tools, Import, Export, Online, and Help. The main window has tabs for Standard Mode, Sites, Contexts, and Requests. The Requests tab is active, displaying a request and response pane. The response pane shows an HTTP/1.1 200 OK status with various headers and the corresponding HTML form code. The Alerts tab is also active, showing a list of 12 alerts, with the first one, 'Absence of Anti-CSRF Tokens (130)', selected. This alert details the URL (http://www.tide.co), risk (Medium), confidence (Low), and provides evidence of the missing token in the form code. The bottom status bar shows 'Alerts 0 3 3 6' and 'Main Proxy: localhost:8080'.

5. Identified vulnerabilities.

In this bug bounty program, I have tested many web applications against various of vulnerabilities. To that I have used lots of tools under each phase of vulnerability assessment. For the ease of identification of vulnerabilities, I have used fully automated tools like OWASP ZAP, Net sparker. In case of further confirmation needed about existence of that identified vulnerability I have used Linux build in tools and frameworks for the double confirmations.

In this journal book I have mentioned all the vulnerabilities I found in each web application and for the reporting purposes of the existence of the vulnerability I have only used most crucial vulnerabilities that I have found in each domain.

A. Domain: Malwarebytes.com

Proof of bug bounty program:

The screenshot shows the Malwarebytes Bug Bounty Program page on Bugcrowd. At the top, there's a logo, the name "Malwarebytes", a tagline "Cyberprotection for every one.", and a "Submit report" button. To the right, it says "Bug Bounty Program Launched on Feb 2023". Below that, it indicates the program is "Managed by HackerOne", "Includes retesting", and "Bounty splitting enabled". There are also "Bookmarked" and "Subscribe" buttons. The main content area has sections for "Rewards" and "Response Efficiency". The "Rewards" section shows four severity levels: Low (yellow), Medium (orange), High (pink), and Critical (red), with corresponding reward ranges: \$20 - \$100, \$100 - \$750, \$750 - \$2,500, and \$2,500 - \$6,000. The "Response Efficiency" section shows response times: 21 hrs (average time to first response) and 2 days (average time to triage). It also highlights that 95% of reports meet response standards based on the last 90 days. At the bottom, there's a note about rewards being based on CVSS 3.0 and examples of lower-severity issues like reflected XSS or RCEs.

I have identified many vulnerabilities in under domain www.malwarebytes.com/. I figured out it has vulnerabilities that listed by OWASP Top 10. And the overall website risk level is **medium**. I used net sparker to identify vulnerabilities in the following domain. And used some of the previously mentioned tools in section. I identified the following OWASP Top vulnerabilities in following domain.

- 1. Security misconfiguration**
- 2. Sensitive data exposure**
- 3. Using components with known vulnerabilities.**

1. Security misconfiguration. -Reported

i. HSTS security errors and warnings

A5 - SECURITY MISCONFIGURATION

 HTTP Strict Transport Security (HSTS) Errors and Warnings	GET	https://www.malwarebytes.com/	MEDIUM
---	-----	---	--------

Under this OWASP category I have identified many vulnerabilities that can occur due to bad implementation of security under domain of <https://www.malwarebytes.com/>.

- Impacts of HSTS errors and warnings.**

1. HSTS faults or warnings indicate that an HTTPS connection is not being properly enforced by the web application. Insecure connections. As a result, users may access the application over insecure HTTP connections, increasing the risk of attackers listening in, meddling with, or intercepting their communications.
2. HSTS failures or warnings can make the web application susceptible to MITM attacks. Attackers can force the browser to communicate over insecure HTTP rather than HTTPS by intercepting the initial HTTP request and altering the response to delete or change the HSTS headers.
3. The website may be unable to create secure connections with compliant browsers due to HSTS issues. Users may get browser errors or warnings as a result, indicating that the connection might not be secure. Users can feel deterred from using the application or think it's less reliable.
4. HSTS faults or warnings may make SSL/TLS's (Secure Sockets Layer/Transport Layer Security) defense against SSL/TLS-stripping attacks less effective. These attacks seek to switch the connection from HTTPS to HTTP, which would enable attackers to eavesdrop on or alter user-app communication.

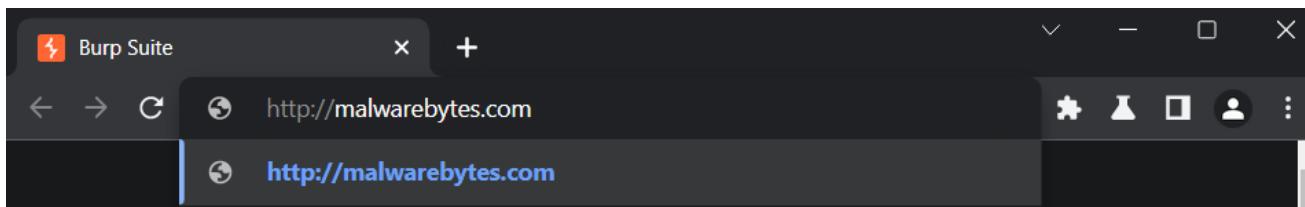

Because of this vulnerability marked as **MEDIUM**. It's a must to address it with a good solution.

- **Steps to reproduce this vulnerability.**

1. Clear the cache in your web browser first before attempting to access your online application. By doing this, you may be sure that all previous HSTS settings have been eliminated and can witness the behavior in its purest form.
2. Access your web application through HTTP: Enter the URL using the HTTP protocol (for example, "http://www.malwarebytes.com") rather than HTTPS to access your web application. This should open a connection that is not secure.
3. After utilizing HTTP to visit the web application, watch your web browser's actions. The browser ought to immediately switch the connection to HTTPS, enforcing a secure connection, if HSTS is properly implemented. However, the browser may show an error message, a warning, or fail to create a secure connection if there are HSTS issues or warnings.
4. Examine the developer tools in the browser by opening them. To access the developer tools, right-click on the webpage and select "Inspect" or "Inspect Element" in most browsers. Look for any HSTS-related error messages, warnings, or console logs.

- **Proof of Concept.**

1. Access web application through HTTP.

```

I have attached the request and response. You can see that it responded to me with a HTTP.it seems preload directive is missing or not enabled.

- **Solutions to the above-mentioned vulnerability (Remedy).**

The first step is to identify the error codes and resolve those problems. The domain must be added to the HSTS preload list after the issues with the HSTS header have been resolved. Browsers automatically connect to the website via HTTPS when the domain is added to the HSTS preload list, preventing users from making HTTPS requests to the server.

The web application needs to be set in accordance with the following requirements before being added to the preload list of the browser.

1. Present a legitimate certificate.
2. If you are listening on port 80, switch all HTTP domains on the same host to HTTPS. Serve every subdomain using HTTPS.
 - If a DNS record for the www subdomain exists, you must support HTTPS for that subdomain.
3. Provide a HSTS header for HTTPS queries on the base domain:
 - The maximum age requirement is 31536000 seconds (one year).
 - It is necessary to specify the included Subdomains directive.
 - Preload directive needs to be mentioned.
 - The HSTS header must be included on the additional redirection that is being served from your HTTPS site, not on the destination page.

2. Sensitive data exposure. – reported

i. Weak ciphers enabled.

	Weak Ciphers Enabled	GET	https://www.malwarebytes.com/	MEDIUM
--	--------------------------------------	-----	---	---------------------

Under this OWASP category I have identified many vulnerabilities that can occur due to bad implementation of security implementations under domain of <https://www.malwarebytes.com/>

- Impacts of HSTS errors and warnings.**

1. So, the effect of allowing weak ciphers during SSL communication is attackers might decrypt the SSL traffic between client and server if they used good mechanism.
2. The online application is more vulnerable to numerous cryptographic attacks with weak ciphers, such as brute force, cipher-text-only, and chosen-plaintext. Attackers can use these flaws to decrypt private information sent between the client and the server.
3. Security requirements and laws may not be followed if weak ciphers are enabled. Strong cryptographic protocols and ciphers are necessary to secure sensitive data according to many security standards, including the General Data Protection Regulation (GDPR) and the Payment Card Industry Data Security Standard (PCI DSS). If these criteria are not met, there may be legal and regulatory repercussions.
4. In comparison to stronger ciphers, some weaker ciphers could have a higher computational cost. The server's processing time and resource use may rise if such ciphers are enabled, which can affect the web application's performance and response times.

Because of this vulnerability marked as **MEDIUM**. It's a must to address it with a good solution.

- **Steps to reproduce this vulnerability.**

1. Must first find the list of ciphers that your web application supports. The SSL/TLS settings on the server are normally setup with this data.
2. There are several internet resources that can scan the SSL/TLS settings of your web application and reveal the ciphers that are enabled. The SSL Server Test from SSL Labs is one such tool (<https://www.ssllabs.com/ssltest/>). The tool will conduct a thorough examination of your SSL/TLS configuration, including the supported ciphers, after you enter the URL of your web application. (<http://www.malwarebytes.com>)
3. Review the scan results when the program has finished its study to find any ciphers that are enabled in your web application that are weak or out-of-date. The program will often give the SSL/TLS configuration a grade or score and point out any flaws or vulnerabilities it discovers.
4. Test cipher negotiation: Run a cipher negotiation test against your web application using a network testing tool like OpenSSL or Nmap. In this test, you'll establish a connection to your web application and watch as the negotiated cipher suite is established during the handshake.
5. Examine the cipher suite that was agreed upon: See if any weak ciphers were chosen for the connection by looking at the results of the encryption negotiation test. Search for any ciphers that are regarded as being brittle, exposed, or dated.
6. Test on various clients: To watch the SSL/TLS handshake, access your web application using various web browsers and client devices. Verify whether weak ciphers are consistently chosen and whether the negotiated cipher suite varies between clients.
7. Validate with vulnerability scanning tools: Conduct a thorough security analysis of your web application using vulnerability scanning tools like Nessus or OpenVAS. These programs may check for SSL/TLS vulnerabilities and offer thorough findings on ciphers with weak security or possible attacks.

- Proof of concept.

[NETSPARKER] SSL Connection

Response

Response Time (ms) : 1 Total Bytes Received : 27 Body Length : 0 Is Compressed : No

[NETSPARKER] SSL Connection

This domain supports following weak ciphers:

- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384 (0xC028)
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 (0xC027)

- **Solutions to the above-mentioned vulnerability (Remedy).**

Solution may differ mechanism used to implement the cipher suite. Can suggest some solutions for Apache HTTP server, Nginx, Microsoft IIS, and node js.

1. Apache

Change the SSLCipherSuite directive in the Apache configuration file (such as httpd.conf or ssl.conf) to only include strong ciphers. Take out of the list any ciphers that are old or weak.

```
SSLCipherSuite HIGH:!aNULL:!MD5:!3DES
```

2. Nginx

Update the ssl_ciphers directive in the Nginx configuration file (such as nginx.conf or ssl.conf) to only contain secure ciphers. Eliminate any ciphers that are weak or exposed.

```
ssl_ciphers 'HIGH:!aNULL:!MD5:!3DES';
```

3. Node js

Your Node.js application's SSL/TLS configuration must be updated. Only safe ciphers should be included in the cipher's parameter of the https.createServer() function.

```
const https = require('https');
const fs = require('fs');

const options = {
  key: fs.readFileSync('path/to/private-key.pem'),
  cert: fs.readFileSync('path/to/certificate.pem'),
  ciphers: 'HIGH:!aNULL:!MD5:!3DES',
};

const server = https.createServer(options, (req, res) => {
  // Server logic
});

server.listen(443);
```

4. Microsoft IIS

For SSL/TLS configuration, use the IIS Manager. Go to your website's "SSL Settings" and, under "Ciphers," only choose strong ciphers. Cross out any weak ciphers from the list.

3. Using components with known vulnerabilities. – reported

i. Possible breach attack -reported.

 [Possible] BREACH Attack	GET Detected	https://www.malwarebytes.com/business/pricing?quantity=%2527	7	MEDIUM
--	-----------------	---	---	--------

Under this OWASP category I have identified a vulnerability called BREACH attack is possible in this web application. It is under the domain of

<https://www.malwarebytes.com/business/pricing?quantity=%2527>.

- Impact of BREACH attack on the web application.**

The result of this vulnerability is that an attacker may be able to use this online application to undertake a BREACH (Browser Reconnaissance & Exfiltration through Adaptive Compression of Hypertext) attack.

It is still possible to carry out this type of attack and to breach the data from the online application due to factors that make the BREACH attack conceivable on this web site, even if it is secured with SSL/TLS protected communication.

1. Information leakage: If a BREACH attack is successful, encrypted HTTPS answers may reveal private data. This includes any private data transmitted within the compressed response body, such as CSRF tokens, session IDs, authentication credentials, and others.
2. Compression feature of HTTP exploited: BREACH makes use of the compression capability of HTTP to lower the size of the response body. An attacker can determine whether certain information is present in the answer by altering the content and tracking changes in the compressed response size.
3. Side-channel attack vector: The BREACH attack uses numerous queries to track changes in the size of compressed answers as a side-channel attack vector. An attacker can obtain sensitive information by monitoring the variations in the compressed response sizes and conducting controlled queries while evaluating these changes.

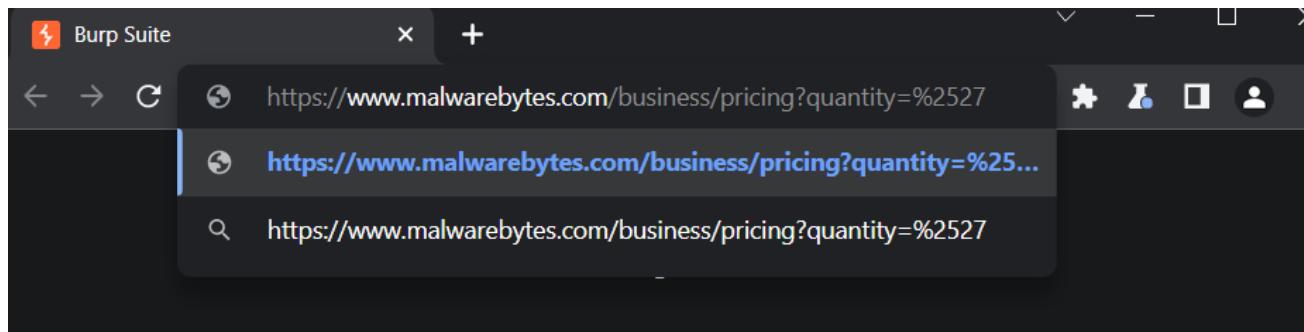

Because of this vulnerability marked as **MEDIUM**. It's a must to address it with a good solution.

- **Steps to reproduce BREACH attack vulnerability.**

Reproduction of this vulnerability must be done in a controlled environment and at your own risk of anything happening.

1. First need to Setup network traffic intercepting tool like burp suite to capture the request and response to such an attack successfully.
2. Determine which pages that send sensitive data, such as CSRF tokens, session IDs, or other private information. In this case I have identified the page **pricing** sends sensitive data in unencrypted manner. (<https://www.malwarebytes.com/business/pricing>)
3. Use a tool or write a script to send carefully constructed requests to the target pages. Change the requests to include patterns or secrets you think might be hidden in the compressed answers.
4. Take note of the compressed response size for each well-constructed request. Keep an eye out for any variations in response size when the request's content or secrets are changed.
5. Compare the response times for various queries with different secret or content variants. Observe any patterns or noteworthy modifications in the compressed answer sizes.
6. Compare the response times for various queries with different secret or content variants. Observe any patterns or noteworthy modifications in the compressed answer sizes.
7. Repeat the procedure to further validate the vulnerability by adjusting the created requests or adding new variations. Analyze the variations in response size and check for consistency in your observations.
8. Verify the correlation between changes in response size and the presence or absence of sensitive information. Check to see if the changes in compressed response size can be reliably seen.

- **Proof of concept.**

- **Solutions to the above-mentioned vulnerability (Remedy).**

1. If possible, disable HTTP level compression.
2. Separate sensitive information from user input
3. Protect vulnerable pages with CSRF token. The Same Site Cookie attribute will mitigate this issue, because to exploit this issue an attacker forces the victim to visit a target website using invisible frames. With the Same Site cookie attribute added, cookies that belong to the target won't be sent with a request that does not include top level navigation.
4. Hide the length of the traffic by adding a random number of bytes to the responses.
5. Add in a rate limit, so that the page maximum is reached five times per minute.
6. Implement per-session, randomized CSRF tokens to stop attackers from successfully launching CSRF attacks. To defend against CSRF attacks, think about employing double-submit cookies or other secure techniques.
7. To defend against additional attack routes that could indirectly expose data, like SQL injection and Cross-Site Scripting (XSS), provide appropriate input validation and output encoding.
8. To identify any unusual behavior or anomalies relating to compression, response times, or data leakage, implement monitoring and intrusion detection systems.

ii. Outdated version of bootstrap (XSS) -reported.

[Out-of-date Version
\(Bootstrap\)](#)

GET

<https://www.malwarebytes.com/js/bootstrap.js>

MEDIUM

Under this OWASP category I have identified this vulnerability too. Identified that this version of bootstrap program is vulnerable to **cross site scripting attacks**. Also, there is considerable amount of record to prove that this version is vulnerable to this XSS attacks. Found this vulnerability under the domain of <https://www.malwarebytes.com/js/bootstrap.js>.

- **Impact of using outdated bootstrap version.**

1. Older versions of Bootstrap can include security flaws that have been found and patched in more recent versions. Attackers may take advantage of these flaws to jeopardize the security of your application. To reduce the danger of such vulnerabilities, it is crucial to maintain updated frameworks and libraries.

► **Bootstrap Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') Vulnerability**

In Bootstrap before 4.1.2, XSS is possible in the collapse data-parent attribute.

Affected Versions

1.0.0 to 3.3.7

► **Bootstrap Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') Vulnerability**

In Bootstrap before 4.1.2, XSS is possible in the data-container property of tooltip.

Affected Versions

1.0.0 to 3.3.7

► **Bootstrap Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') Vulnerability**

In Bootstrap 3.x before 3.4.0 and 4.x-beta before 4.0.0-beta.2, XSS is possible in the data-target attribute, a different vulnerability than CVE-2018-14041.

► **Bootstrap Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') Vulnerability**

In Bootstrap before 3.4.0, XSS is possible in the tooltip data-viewport attribute.

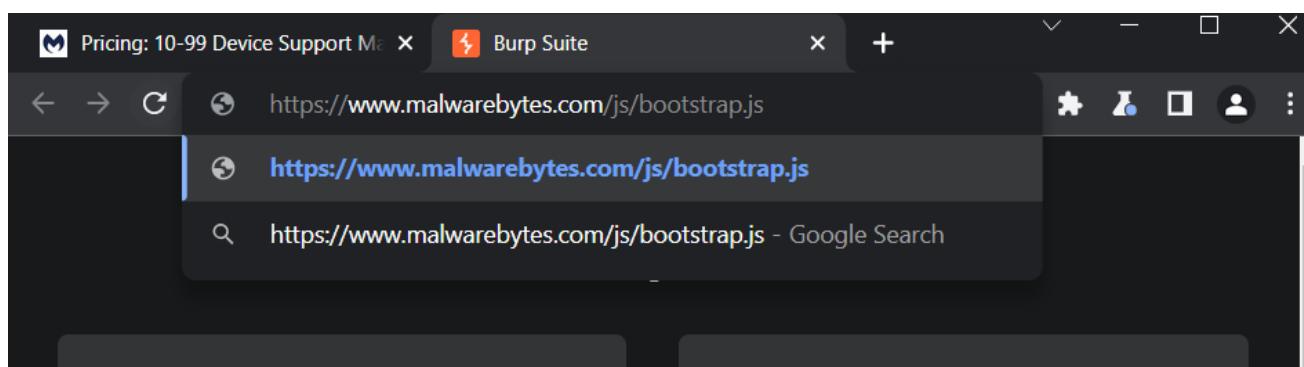

2. Updates for Bootstrap frequently include new features, improvements, and additions. You lose out on these upgrades if you continue to use an outdated version, which restricts the functionality and potential of your web application. The most recent responsive design features, component updates, bug fixes, and other advancements made in more recent versions might not be available to you.
3. Performance improvements in Bootstrap's latest iterations frequently include improved code organization, smaller file sizes, and faster rendering. You can lose out on these improvements if you're using an outdated version, which will make the user experience slower and less effective.

Because of this vulnerability marked as **MEDIUM** It's a must to address it with a good solution.

- **Steps to reproduce this vulnerability.**

1. Examine the source code of the page.
 - Launch a web browser and access the web application.
 - Open the browser's developer tools by selecting "Inspect" or "Inspect Element" from the context menu when you right-click on the web page.
 - Search the page source code for references to Bootstrap files.
2. Verify Bootstrap's version:
 - Look for the Bootstrap-related CSS and JavaScript files in the page's source code.
 - Search for files with "bootstrap" or "bootstrap.min" and a ".css" or ".js" ending.
 - Determine whether the filenames or contents contain the version number.
3. Referencing the documentation for Bootstrap
 - Go to the documentation page on the official Bootstrap website (getbootstrap.com).
 - Search for the documentation for the version that you noted in the prior step.
 - Compare the code used in your web application with the features, elements, and syntax stated in the documentation.
4. Also, the versions of the libraries used in a web application, including Bootstrap, can be determined via automated methods. Outdated library versions can be found with the help of tools like Retire.js, Dependency Check, or built-in security scanners in web development frameworks.

- **Proof of Concept.**

```
/*
 * Bootstrap v3.3.5 (http://getbootstrap.com)
 * Copyright 2011-2015 Twitter, Inc.
 * Licensed under the MIT license
 */

if (typeof jQuery === 'undefined') {
    throw new Error('Bootstrap\'s JavaScript requires jQuery')
}

+

function($) {
    'use strict';
    var version = $.fn.jquery.split(' ')[0].split('.');
    if ((version[0] < 2 && version[1] < 9) || (version[0] == 1 && version[1] == 9 && version[2] < 1))
    {
        throw new Error('Bootstrap\'s JavaScript requires jQuery version 1.9.1 or higher')
    }
}(jQuery);

/* =====
 * Bootstrap: transition.js v3.3.5
 * http://getbootstrap.com/javascript/#transitions
 * =====
 * Copyright 2011-2015 Twitter, Inc.
 * Licensed under MIT (https://github.com/twbs/bootstrap/blob/master/LICENSE)
 * ===== */

```

```
/*

 * Copyright 2011-2015 Twitter, Inc.
 * Licensed under the MIT license
 */
```

The screenshot shows the official Bootstrap website at <https://getbootstrap.com>. The page features a large purple header with a white 'B' icon. Below the header, a yellow button says 'New in v5.3' with the text 'Color mode support, expanded color palette, and more!'. A large white 'B' icon is centered on a dark background. The main heading reads 'Build fast, responsive sites with Bootstrap'. Below it, a dark box contains the command '\$ npm i bootstrap@5.3.0-alpha3'. A blue button labeled 'Read the docs' is visible. At the bottom, there's a footer with links to 'v5.3.0-alpha3', 'Download', 'v4.6.x docs', and 'All releases'. The URL <https://blog.getbootstrap.com> is also present.

- **Solutions to the above-mentioned vulnerability (Remedy).**

1. Find the most recent stable Bootstrap version, then update your web application to use it. New features, performance enhancements, security updates, and bug fixes are often included in the most recent versions. To ensure a seamless move to the new version, follow the migration guides and documentation for Bootstrap.
2. If updating to the most recent version is not immediately possible, look for any security updates or Bootstrap-specific changes. Patches for known vulnerabilities may have been released by Bootstrap or the development community. To fix the security flaws in your current version, apply these updates.
3. Update all your dependencies and libraries, including Bootstrap. This makes it possible to guarantee that your web application makes use of the most recent security updates and features. Check for updates frequently, and plan maintenance windows to update libraries as needed.
4. Keep up with any Bootstrap-related security warnings or vulnerability announcements. To get updates on new vulnerabilities and patches, join security newsletters or follow trustworthy sources. Apply any security updates to your web application as soon as possible.

B. Domain: Inmobi.com

Proof of bug bounty program:

The screenshot shows the InMobi bug bounty program page on the HackerOne platform. At the top, there's a blue header bar with the InMobi logo and a "Submit report" button. Below the header, there's a summary section with the following details:

- InMobi**
- InMobi is an Indian multinational mobile advertising technology company. InMobi subsidiaries includes Glance, Roposo, Koral, Shop101.
- <https://www.inmobi.com> · @InMobi
- Vulnerability Disclosure Program Launched on Dec 2021
- Managed by HackerOne

Below this summary, there are two metrics: "Reports resolved" (32) and "Assets in scope" (16). Further down, there are links for "Policy", "Scope" (which is highlighted in pink), "Hacktivity", "Thanks", and "Updates (0)".

The main content area is divided into two columns. The left column, under "Policy", contains sections for "About Us" and "Vulnerabilities". The "About Us" section describes InMobi as the world's leading Marketing Cloud, driving real connections between brands and consumers. It also mentions InMobi's recognition as a 2019 CNBC Disruptor 50 company and as Fast Company's 2018 Most Innovative Companies. The "Vulnerabilities" section states that InMobi Group looks forward to working with the security community to find vulnerabilities in order to keep our businesses and customers safe.

The right column, under "Response Efficiency", provides statistics: an average time to first response of 21 hours, an average time to triage of 2 months, and 76% of reports meeting response standards. This data is based on the last 90 days.

I have identified many vulnerabilities in under domain www.inmboi.com/. I figured out it has vulnerabilities that listed by OWASP Top 10. And the overall website risk level is **high**. I used net sparker to identify vulnerabilities in the following domain. And used some of the previously mentioned tools in section. I identified the following OWASP Top vulnerabilities in following domain.

- 1. Sensitive Data exposure**
- 2. Using components with known vulnerabilities.**

5/16/2023 7:26:48 PM (UTC+05:30)

OWASP Top Ten 2017 Report

Information	1
TOTAL	8

1. Sensitive data exposure. -Reported

i. Session cookie not marked as secure.

[Session Cookie Not
Marked as Secure](#)

GET

https://www.inmobi.com/user/account_info.json

HIGH

Under this OWASP category I have identified many vulnerabilities like sensitive data exposure that can occur due to bad implementation of security implementations under domain of

https://www.inmobi.com/user/account_info.json

I have identified while scanning the target domain it is sending the session cookie over a HTTPS enabled connection without marking session cookie as secure. Because of this cookie can be stolen by the attacker by intercepting traffic successfully as **MIMT (Man in the middle attack)**. Because of this attacker can still steal the session cookie and can hijack the session of the victim successfully.

If attacker carries and man in the middle attack, he can force the victim to make HTTP request to the web application to steal the Cookie.

• Impact of not marking session cookie as secure.

1. The session cookie can be transmitted through unencrypted HTTP connections rather than HTTPS connections if the "secure" tag is not set. This makes it possible for attackers using MitM attacks to intercept the cookie. Attackers may listen in on the conversation and take the session cookie to access the user's session without authorization.
2. An attacker can obtain the user's session identifier using an unsecured session cookie by taking advantage of flaws like session sniffing or session hijacking. Once the attacker has the session identifier, they can use it to assume the user's identity, log into their account, and take actions on their behalf.
3. Insecure session cookies may not meet regulatory compliance standards like the General Data Protection Regulation (GDPR) or Payment Card Industry Data Security Standard (PCI DSS). The absence of the "secure" characteristic may be flagged as non-compliant by security audits as a vulnerability.
4. Failure to declare the session cookie as secure can reduce user confidence in the security of the online application. Users might be reluctant to conduct sensitive acts or transactions on the website, which could harm the app's credibility and reputation.

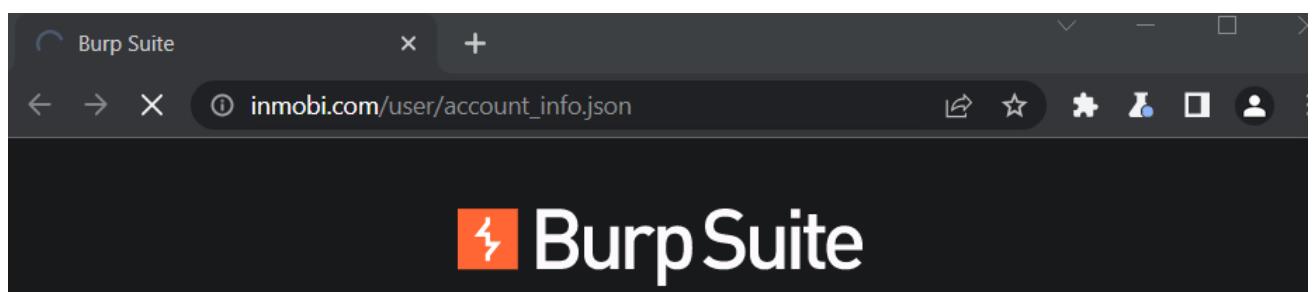

Because of this vulnerability marked as **High** It's a must to address it with a good solution.

- **Steps to reproduce this vulnerability.**

1. Start by configuring two unique browsers, Chrome and Firefox, or browser profiles, or by using two distinct devices.
2. Make sure you are logged into your user account in one of the browsers or devices before opening the web application in both.
3. To record the network traffic between the browser and the web server, use a network analysis program like Wireshark.
4. Use a proxy tool like Burp Suite to intercept the login request in the second browser or device when you are not logged in.
5. Alter the obtained login request such that the session cookie is obtained. You can accomplish this by copying the session ID value from the "Set-Cookie" header.
6. To set the value of the session cookie that was captured, open the developer tools on the second browser or device and run the JavaScript script.
7. Use the second browser or device to reload the page or move to a different page inside the online application.
8. If the session hijacking is successful, the web application might acknowledge the session cookie as legitimate and provide you access to the user account without requesting a login.

- **Proof of Concept.**

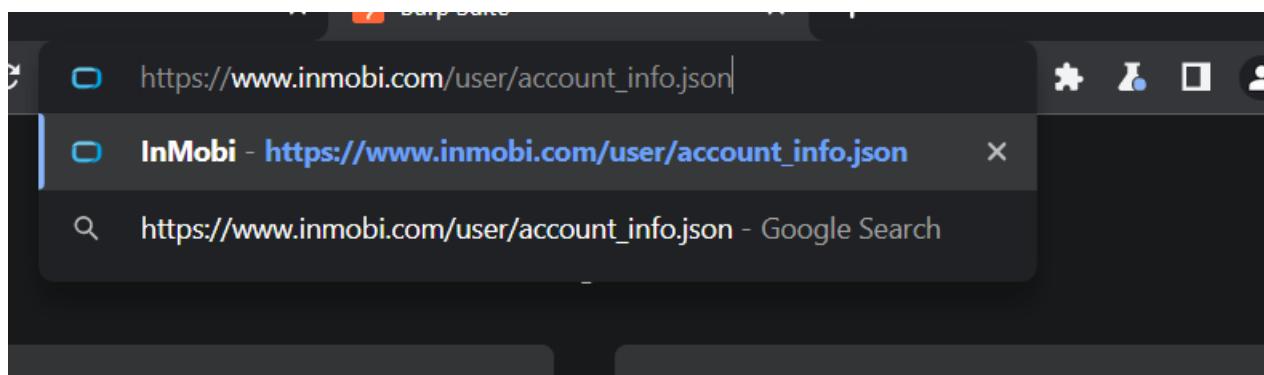

Logging to the web application using legitimate credentials.

Getting the session cookie to hijack the session for legitimate user.

- **Solutions to the above-mentioned vulnerability (Remedy).**

1. Make that the "Secure" attribute is set on the session cookie. This attribute tells the browser to send cookies exclusively over HTTPS-encrypted connections. By setting this attribute, you can reduce the chance of an attacker intercepting the session cookie by preventing its transmission via insecure channels.

```
session_set_cookie_params([
    'secure' => true, // Ensure cookie is only sent over HTTPS
    'httponly' => true, // Restrict cookie access to HTTP requests
    'samesite' => 'Lax', // Enforce same-site policy
]);
```

2. Make sure that HTTPS is being used to deliver your complete web application. This guarantees that all communication, including the transmission of session cookies, is encrypted between the client and server. To enforce secure connections, configure your web server to forward all HTTP requests to HTTPS.
3. Use HSTS to tell the browser to always communicate with your web application via HTTPS. This helps lower the danger of session cookie interception by preventing users from visiting your site using unsecured HTTP connections.

```
Strict-Transport-Security: max-age=31536000; includeSubDomains
```

4. If a significant event occurs, such as a successful login, password change, or privilege elevation, implement a way to regenerate the session identification. Even if an attacker succeeds in stealing a session cookie, this helps to lessen the effects of session hijacking.
5. Implement a technique to regularly re-authenticate users by asking them to do so after a specific period of inactivity or at predetermined intervals. Even if an attacker obtains access to a legitimate session cookie, this can lessen the possibility of session hijacking.

ii. Source code disclosure PHP.

[Possible] Source Code
Disclosure (PHP)

GET

<https://www.inmobi.com/company/press>

MEDIUM

Under this OWASP category I have identified many vulnerabilities like sensitive data exposure that can occur due to bad implementation of security implementations under domain of <https://www.inmobi.com/company/press>

- **Impact of source code disclosure.**

I discovered a PHP code leak because of this scan. Depending on the sort of source code that was leaked, the impact may include the exposure of the internal workings and business logic of the application, as well as database connection strings, usernames, and passwords.

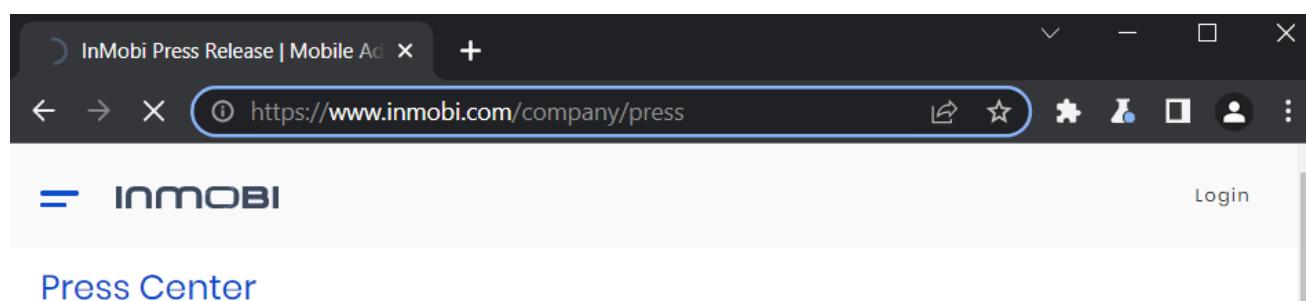

1. the database or other data sources can be accessed. It may be able to read, update, or delete arbitrary data from the database depending on the privileges of the account determined from the source code.
2. To fully operate the application, acquire access to password-protected administrative tools including dashboards, management consoles, and admin panels.
3. Investigate the source code for input validation issues and logic flaws to develop additional attacks.
4. The exposed source code can be altered by attackers to add backdoors, logic bombs, or other malicious code. Because of this, they may be able to obtain unauthorized access, alter data, take unlawful action, or even launch an attack on users or other systems using your web application.
5. Leaked source code can reveal sensitive data, including API keys, database logins, encryption keys, and other private information. Attackers may use this information to launch additional assaults, obtain illegal access to databases, or jeopardize the security of other systems linked to your web application.

Because of this vulnerability marked as **medium** It's a must to address it with a good solution.

- **Step to reproduce this vulnerability.**

1. Find the specific PHP file or exposed PHP code by using code analysis tools, code reviews, or log analysis.
2. To find the main reason for the source code leak, employ security scanning tools or a manual inquiry. Misconfigured server settings, unsafe file permissions, an application vulnerability, or other elements could be to blame. OWASP ZAP, Burp Suite, and Nikto are a few examples of tools that might assist in spotting potential vulnerabilities.
3. Utilize applications like VirtualBox, VMware, or Docker to create a local or isolated testing environment. You can use this to replicate and examine the vulnerability without having an adverse effect on the production system.
4. To duplicate the situation in which the source code fragment is exposed, modify the server settings, or take advantage of the vulnerability. To exploit vulnerabilities or replicate misconfigurations, you can utilize programs like Metasploit, OWASP ZAP, or your own scripts.
5. Access the weak PHP file or exposed fragment using a web browser or an HTTP client program like cURL or Postman. In the address bar or as part of the request, type the URL or path to the PHP file.
6. Verify that the PHP source code snippet is available and leaked. Examine the response in the browser or use programs like Burp Suite, ZAP, or Wireshark to analyze the server response. Verify that the code is being exposed as expected by looking at the content the server has returned.

- **Proof of concept.**

- **Solutions to the above-mentioned vulnerability (Remedy).**

As solutions there are lots of ways that can achieve the expected security about source code disclosure. Among them there are some methods that can be mentioned as good remedy methods.

1. Verify precisely which portions of the source code are really leaked; in certain cases, this may not be feasible because of the restrictions of this sort of vulnerability. Verify that this feature was not intended.
2. Remove any sensitive data from the source code files, including API keys, database logins, and other private information. Use the necessary techniques (e.g., environment variables) to incorporate sensitive information in the PHP files by storing it in a secure configuration file that isn't in the web root directory.
3. If it's a file that the application needs, modify its permissions to bar anyone from accessing it. Remove it from the web server if it isn't.
4. Verify that all recent security fixes have been installed on the server.
5. Delete all backup and temporary files from the web server.
6. Use secure code deployment techniques to reduce the possibility of source code leakage. Using secure file transfer protocols (such as SFTP and SCP) and adhering to secure coding standards, such as input validation, output encoding, and defense against code injection attacks, are examples of how to do this.

2. Using components with known vulnerabilities.

i. Outdated jQuery version (UI Autocomplete/UI Dialog/UI Tool tip.)

	Out-of-date Version (jQuery UI Autocomplete)	GET	https://www.inmobi.com/	MEDIUM
	Out-of-date Version (jQuery UI Dialog)	GET	https://www.inmobi.com/	MEDIUM
	Out-of-date Version (jQuery UI Tooltip)	GET	https://www.inmobi.com/	MEDIUM

I have identified the vulnerability that falls under OWASP top 10 list as Using components with known vulnerabilities. I found it under domain of <https://www.inmobi.com/>.

- Impact of using outdated jQuery version.**

1. Since this is an older version of the software series there are some records that mentioned vulnerabilities in the following version vulnerabilities. Says that this version is vulnerable to cross site scripting attacks (XSS).

jQuery UI Autocomplete Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') Vulnerability

jQuery-UI is the official jQuery user interface library. Prior to version 1.13.0, accepting the value of the `altField` option of the Datepicker widget from untrusted sources may execute untrusted code. The issue is fixed in jQuery UI 1.13.0. Any string value passed to the `altField` option is now treated as a CSS selector. A workaround is to not accept the value of the `altField` option from untrusted sources.

Affected Versions

1.12.0 to 1.12.1

jQuery UI Autocomplete Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') Vulnerability

jQuery-UI is the official jQuery user interface library. Prior to version 1.13.0, accepting the value of the `of` option of the `\$.position()` util from untrusted sources may execute untrusted code. The issue is fixed in jQuery UI 1.13.0. Any string value passed to the `of` option is now treated as a CSS selector. A workaround is to not accept the value of the `of` option from untrusted sources.

Affected Versions

1.12.0 to 1.12.1

jQuery UI Autocomplete Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting') Vulnerability

jQuery-UI is the official jQuery user interface library. Prior to version 1.13.0, accepting the value of various `*Text` options of the Datepicker widget from untrusted sources may execute untrusted code. The issue is fixed in jQuery UI 1.13.0. The values passed to various `*Text` options are now always treated as pure text, not HTML. A workaround is to not accept the value of the `*Text` options from untrusted sources.

2. In older variations of jQuery, performance optimizations and efficiency enhancements may not be present. This may result in sluggish page loads, longer response times, or wasteful use of system resources. The user experience may suffer as a result, particularly when working with huge datasets or intricate UI interactions.
3. Older jQuery releases might not have important security improvements added since then. Improved output encoding, input sanitization, and defenses against typical security risks are a few examples of these improvements. You could unintentionally impair your application's security safeguards and increase its vulnerability to attacks if you use an outdated version.
4. Your application's attack surface is increased if you're still using an old version of jQuery. Since attackers are aware of the flaws in certain versions, they can target them specifically to undermine the security of your application. By failing to update to the most recent version of jQuery, you give attackers a known point of entry for exploitation.

Because of this vulnerability marked as **medium** It's a must to address it with a good solution.

- **Step to reproduce this vulnerability.**

1. Identify the feature that uses the jQuery version that is vulnerable. Concentrate on locations that receive user input, including input fields, form submissions, or AJAX calls that communicate with the exposed jQuery functions. Can use burp suite, chrome dev tools or code editor.
2. To create a malicious payload including JavaScript code, use Burp Suite, OWASP ZAP, or online XSS payload generators. For example, `<script>alert('XSS') </script>`
3. To access the correct page of your web application, use a web browser (such as Google Chrome, Firefox, or Microsoft Edge). Place the carefully constructed payload in input forms, query parameters, or any other areas that take user input. To change HTML or JavaScript code dynamically, utilize the browser developer tools.
4. Once the payload has been injected, observe the browser's actions. Check to see if the payload is performed and if any unexpected activity, such as an alert box, takes place. To verify that the payload was successfully executed, you can analyze network requests and the DOM with the aid of browser development tools. To inject can use burp suite or OWASP ZAP or any.
5. To make sure that the vulnerability is consistent, run the test again with various payload changes and more scenarios. Check to see if the XSS vulnerability can be continuously reproduced and if it compromises the security of your application.

• Proof of existence of vulnerability.

- **Solutions to the above-mentioned vulnerability (Remedy).**

1. Upgrade to a more recent and secure version of jQuery. Update your application to comply with the most recent stable version by visiting the jQuery website or GitHub repository. You can gain access to bug fixes, security patches, and better code quality by updating to a newer version.
2. To reduce the danger of cross-site scripting (XSS) attacks, use a content security policy. You can set a policy with CSP that limits the kinds of content that can be loaded and run on your web pages. Malicious scripts that are injected using weak components can be stopped from running by properly specifying CSP directives.
3. Conduct routine security audits and code reviews of the front-end code of your web application, paying particular attention to the jQuery usage and the custom code for the dialog, autocomplete, and tooltip functionalities. Keep an eye out for any potential security holes and take aggressive measures to fix them.

C. Domain: [merck.com](#)

Proof of bug bounty program:

The screenshot shows the Merck & Co., Inc. Vulnerability Disclosure Program page on the HackerOne platform. At the top, it displays the company name "Merck & Co., Inc., Rahway, NJ, USA" and a "Submit report" button. Below this, there are two metrics: "Reports resolved" (280) and "Assets in scope" (3). To the right, it says "Vulnerability Disclosure Program" was "Launched on Mar 2023" and is "Managed by HackerOne". There are also "Bookmarked" and "Subscribe" buttons. Below the header, there are navigation links: Policy, Scope (New!), Hacktivity, Thanks, and Updates (0). The main content area is divided into two sections: "Policy" and "Response Efficiency". The "Policy" section contains an "Introduction" paragraph about the company's commitment to safety and security, followed by guidelines for reporting vulnerabilities. The "Response Efficiency" section provides metrics: 9 hrs (average time to first response), 2 days (average time to triage), and 3 months (average time to resolution), along with a 96% success rate in meeting response standards over the last 90 days.

I have identified many vulnerabilities in under domain www.merck.com/. I figured out it has vulnerabilities that listed by OWASP Top 10. And the overall website risk level is **high**. I used net sparker to identify vulnerabilities in the following domain. And used some of the previously mentioned tools in section. I identified the following OWASP Top vulnerabilities in following domain.

1. Using components with known vulnerabilities.

5/17/2023 12:59:26 AM (UTC+05:30)

OWASP Top Ten 2017 Report

🔗 https://www.merck.com/

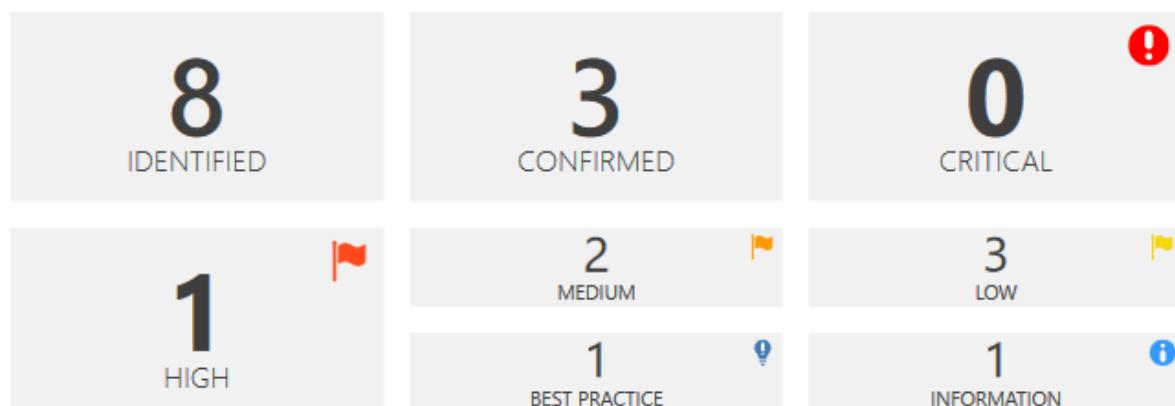

Scan Time : 5/5/2023 9:19:37 PM (UTC+05:30)
Scan Duration : 00:00:07:14
Total Requests : 6,821
Average Speed : 15.7r/s

Risk Level:
HIGH

Explanation

This report is generated based on OWASP Top Ten 2017 classification.

There are 12 more vulnerabilities that are not shown below. Please take a look at the detailed scan report to see them.

1. Using components with known vulnerabilities.

i. Outdated WordPress (possible SSRF).

	Out-of-date Version (WordPress)	GET	https://www.merck.com/wp-includes/images/arrow-pointer-blue.png	HIGH
---	---	-----	---	-------------------

Under this OWASP category I have identified vulnerabilities like Using components with known vulnerabilities that can occur due to bad implementation of security implementations under domain of <https://www.merck.com/wp-includes/images/arrow-pointer-blue.png>

Detected that web application using outdated word press. Word press is a free and open-source content management system (CMS) based on PHP and MySQL.

- Impact of using an outdated WordPress**

1. WordPress versions that are out of date are more likely to include security flaws. Attackers may use these flaws to modify data, execute arbitrary commands, introduce malicious code, or obtain unauthorized access. The longer a version is out-of-date, the more likely it is that automated scripts and attackers searching for known vulnerabilities will target it.

WordPress Time-of-check Time-of-use (TOCTOU) Race Condition Vulnerability

WordPress is affected by an unauthenticated blind SSRF in the pingback feature. Because of a TOCTOU race condition between the validation checks and the HTTP request, attackers can reach internal hosts that are explicitly forbidden.

Affected Versions

6.0.3 to 6.1.1

WordPress Uncontrolled Resource Consumption Vulnerability

WordPress through 6.1.1 depends on unpredictable client visits to cause wp-cron.php execution and the resulting security updates, and the source code describes "the scenario where a site may not receive enough visits to execute scheduled tasks in a timely manner," but neither the installation guide nor the security guide mentions this default behavior, or alerts the user about security risks on installations with very few visits.

Affected Versions

6.0.3 to 6.1.1

2. You cannot access the most recent security fixes and upgrades if your WordPress installation is out of date. These upgrades fix known security flaws and aid in shielding your website from prospective attackers. You expose your website to known security dangers by not updating your WordPress version.
3. It's possible that performance optimizations added to current WordPress versions are absent in older versions. It's possible that outdated versions lack performance advancements like caching techniques, database improvements, or code optimizations. As a result, the functionality of your

website can be compromised, which might result in slower page loads, a worse user experience, and even lower search engine results.

4. Official support for obsolete WordPress versions gradually decreases over time. This implies that it can be difficult to get support from the WordPress community or developers if you run into any problems or need help. If you continue using an outdated version, you can lose access to vital support tools.

Because of this vulnerability marked as **High** It's a must to address it with a good solution.

- **Step to reproduce this vulnerability.**

1. Choose the precise WordPress version web application uses and Keep track of the precise version that is vulnerable to uncontrolled resource use.
2. On your website, produce a heavy load or carry out actions that use plenty of resources. This can be done in several ways, including:
 - using tools for load testing, such as Apache JMeter, Siege, or Locust, to simulate a high volume of concurrent user requests. running resource-intensive plugins or themes, or creating posts, uploading files, and performing several simultaneous tasks.
 - sending several queries to vulnerable endpoints or features in a targeted manner.
3. While simulating a heavy load, keep an eye on how your testing environment is using its resources. Monitor database connections and queries, as well as the server's CPU, memory, and disk consumption.
4. Look for evidence that the system resources are not being correctly managed or controlled, such as performance degradation, sluggish response times, server crashes, excessive memory utilization, or other signals.
5. To find any resource-related issues, such as memory leaks, database connection restrictions, or ineffective resource utilization, analyze server logs, performance metrics, and error reports.

- Proof of existence of vulnerability.

Identified Versions

- 6.0.3, 6.0.2

Latest Version

- 6.0.3 (in this branch)

Vulnerability Database

- Result is based on 05/03/2023 20:30:00 vulnerability database content.

Request

```
GET /wp-includes/images/arrow-pointer-blue.png HTTP/1.1

Response Time (ms) : 286.9638 Total Bytes Received : 1917 Body Length : 1569 Is Compressed : No

Binary response detected, response has not saved.

- Solutions to the above-mentioned vulnerability (Remedy).

1. Updating your WordPress installation to the most recent stable version is the best solution. Security patches, bug fixes, and performance enhancements are frequently included in updates.
2. Check the code of your WordPress theme and plugins for any possible security flaws. usage secure coding techniques to reduce the risk of common vulnerabilities like XSS (Cross-Site Scripting) and SQL injection. These techniques include input validation, output sanitization, and effective usage of WordPress APIs.
3. To add an extra layer of security to your WordPress website, install and set up reliable security plugins. Strong password requirements, the implementation of firewall rules, the detection and mitigation of common vulnerabilities, and routine security scans can all be assisted by these plugins.
4. To find any potential vulnerabilities in your WordPress installation, themes, or plugins, do vulnerability checks periodically using specialist tools like WPScan or security plugins. As soon as vulnerabilities are found, update or replace the impacted components.

D. Domain: Curl.se

Proof of bug bounty program:

The screenshot shows the curl.se bug bounty program page. At the top, there's a logo of two green and blue pipes, the text "curl", and a brief description: "curl is a computer software project providing a library and command-line tool for transferring data using various protocols." A pink "Submit report" button is on the right. To the right, it says "Bug Bounty Program Launched on Apr 2019". Below this, there are stats: "Reports resolved 54", "Assets in scope 1", and "Average bounty \$700-\$800". On the far right are "Bookmark" and "Subscribe" buttons. Below these stats, there are tabs: Policy, Scope (which is selected and highlighted in pink), Hacktivity, Thanks, and Updates (0). The main content area has two sections: "Rewards" and "Response Efficiency". The "Rewards" section shows reward levels for Low (\$480), Medium (\$2,400), High (\$6,000), and Critical (\$12,000) vulnerabilities. It also notes that rewards are graciously donated by the Internet Bug Bounty. The "Response Efficiency" section shows average times: about 1 hr for first response, 2 days for triage, and 17 days for bounty. At the bottom, it says "Last updated on May 20, 2023. View changes".

I have identified many vulnerabilities in under domain www.curl.se/. I figured out it has vulnerabilities that listed by OWASP Top 10. And the overall website risk level is **Critical**. I used net sparker to identify vulnerabilities in the following domain. And used some of the previously mentioned tools in section. I identified the following OWASP Top vulnerabilities in following domain.

- 1. Using components with known vulnerabilities.**
- 2. Sensitive data exposure.**

1. Using components with known vulnerabilities. -Reported

i. Out of date version PHP (7.4.10).

	Out-of-date Version (PHP)	GET	https://curl.se/mail/lib-2008-01/att-0240/httponly.php	CRITICAL
--	---	-----	---	--

Under this OWASP category I have identified many vulnerabilities like using components with known vulnerabilities and sensitive data exposure that can occur due to bad implementation security under domain of <https://curl.se/mail/lib-2008-01/att-0240/httponly.php>

Also detected that this web application is using an outdated, also vulnerable PHP version to full fill their back-end processes. Figured out that this version of PHP is vulnerable to following attacks. Also, many features are depreciated in this version of PHP.

- **Impacts of using outdated PHP.**

1. Known weaknesses in outdated PHP versions may exist and be used by attackers. Unauthorized access, remote code execution, SQL injection, cross-site scripting (XSS), and other sorts of attacks could be made possible by these vulnerabilities.

PHP Out-of-bounds Write Vulnerability

In PHP versions 7.3.x below 7.3.29, 7.4.x below 7.4.21 and 8.0.x below 8.0.8, when using Firebird PDO driver extension, a malicious database server could cause crashes in various database functions, such as `getAttribute()`, `execute()`, `fetch()` and others by returning invalid response data that is not parsed correctly by the driver. This can result in crashes, denial of service or potentially memory corruption.

PHP CVE-2022-31629 Vulnerability

In PHP versions before 7.4.31, 8.0.24 and 8.1.11, the vulnerability enables network and same-site attackers to set a standard insecure cookie in the victim's browser which is treated as a `__Host-` or `__Secure-` cookie by PHP applications.

PHP Use After Free Vulnerability

In PHP versions 7.4.x below 7.4.28, 8.0.x below 8.0.16, and 8.1.x below 8.1.3, when using filter functions with `FILTER_VALIDATE_FLOAT` filter and min/max limits, if the filter fails, there is a possibility to trigger use of allocated memory after free, which can result in crashes, and potentially in overwrite of other memory chunks and RCE. This issue affects: code that uses `FILTER_VALIDATE_FLOAT` with min/max limits.

PHP Buffer Copy without Checking Size of Input ('Classic Buffer Overflow') Vulnerability

In PHP versions 7.4.x below 7.4.30, 8.0.x below 8.0.20, and 8.1.x below 8.1.7, when `pdo_mysql` extension with `mysqlnd` driver, if the third party is allowed to supply host to connect to and the password for the connection, password of excessive length can trigger a buffer overflow in PHP, which can lead to a remote code execution vulnerability.

PHP Release of Invalid Pointer or Reference Vulnerability

In PHP versions 7.4.x below 7.4.30, 8.0.x below 8.0.20, and 8.1.x below 8.1.7, when using Postgres database extension, supplying invalid parameters to the parametrized query may lead to PHP attempting to free memory using uninitialized data as pointers. This could lead to RCE vulnerability or denial of service.

PHP Integer Overflow or Wraparound Vulnerability

The Keccak XKCP SHA-3 reference implementation before fdc6fef has an integer overflow and resultant buffer overflow that allows attackers to execute arbitrary code or eliminate expected cryptographic properties. This occurs in the sponge function interface.

PHP Out-of-bounds Read Vulnerability

In PHP versions prior to 7.4.33, 8.0.25 and 8.2.12, when using imageloadfont() function in gd extension, it is possible to supply a specially crafted font file, such as if the loaded font is used with imagechar() function, the read outside allocated buffer will be used. This can lead to crashes or disclosure of confidential information.

PHP Uncontrolled Recursion Vulnerability

In PHP versions before 7.4.31, 8.0.24 and 8.1.11, the phar uncompressor code would recursively uncompress "quines" gzip files, resulting in an infinite loop.

PHP Out-of-bounds Write Vulnerability

In PHP versions 7.3.x up to and including 7.3.31, 7.4.x below 7.4.25 and 8.0.x below 8.0.12, when running PHP FPM SAPI with main FPM daemon process running as root and child worker processes running as lower-privileged users, it is possible for the child processes to access memory shared with the main process and write to it, modifying it in a way that would cause the root process to conduct invalid memory reads and writes, which can be used to escalate privileges from local unprivileged user to the root user.

PHP Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal') Vulnerability

In PHP versions 7.3.x below 7.3.31, 7.4.x below 7.4.24 and 8.0.x below 8.0.11, in Microsoft Windows environment, ZipArchive::extractTo may be tricked into writing a file outside target directory when extracting a ZIP file, thus potentially causing files to be created or overwritten, subject to OS permissions.

PHP Improper Input Validation Vulnerability

In PHP versions 7.3.x below 7.3.29, 7.4.x below 7.4.21 and 8.0.x below 8.0.8, when using URL validation functionality via filter_var() function with FILTER_VALIDATE_URL parameter, an URL with invalid password field can be accepted as valid. This can lead to the code incorrectly parsing the URL and potentially leading to other security implications - like contacting a wrong server or making a wrong access decision.

PHP Other Vulnerability

In PHP versions 7.3.x below 7.3.33, 7.4.x below 7.4.26 and 8.0.x below 8.0.13, certain XML parsing functions, like simplexml_load_file(), URL-decode the filename passed to them. If that filename contains URL-encoded NUL character, this may cause the function to interpret this as the end of the filename, thus interpreting the filename differently from what the user intended, which may lead it to reading a different file than intended.

PHP Improper Input Validation Vulnerability

In PHP versions 7.3.x below 7.3.26, 7.4.x below 7.4.14 and 8.0.0, when validating URL with functions like filter_var(\$url, FILTER_VALIDATE_URL), PHP will accept an URL with invalid password as valid URL. This may lead to functions that rely on URL being valid to mis-parse the URL and produce wrong data as components of the URL.

PHP NULL Pointer Dereference Vulnerability

In PHP versions 7.3.x below 7.3.27, 7.4.x below 7.4.15 and 8.0.x below 8.0.2, when using SOAP extension to connect to a SOAP server, a malicious SOAP server could return malformed XML data as a response that would cause PHP to access a null pointer and thus cause a crash.

2. The PHP development team no longer provides security updates and patches for out-of-date PHP versions. This implies that any newly found flaws or problems won't be fixed, making your application more vulnerable to assaults.
3. Certain features or functions are designated as deprecated in PHP versions and then finally removed in newer versions. Utilizing an out-of-date PHP version puts your codebase at risk of future support and maintenance issues because it depends on deprecated features.

Because of this vulnerability marked as **Critical** It's a must to address it with a good solution.

- **Step to reproduce this vulnerability.**

1. Determine the specific outdated PHP version you want to test. Note the exact version number.
2. Make a test script that includes the code patterns that are relevant to the found vulnerabilities. To achieve this, code fragments that cause integer overflow, wraparound, or use-after-free behavior may need to be created.
3. To create inputs that result in integer overflow or wraparound scenarios, use fuzzing frameworks that you have created or tools like the AFL (American Fuzzy Lop). To examine the code and identify flaws, these tools produce test inputs automatically.
4. To find use-after-free vulnerabilities, use programs like AddressSanitizer (ASan) or Valgrind (Memcheck). These tools can be used to detect erroneous memory accesses brought on using released objects.
5. To exploit the vulnerabilities found, run the test script or use the fuzzing tool's generated inputs.
6. Watch how the PHP interpreter behaves while the test is running. Keep an eye out for errors, crashes, or other strange output that can point to a vulnerability.
7. Examine how the vulnerabilities affect the PHP interpreter and the system. Examining crash logs, memory dumps, or error messages may be necessary to gauge the seriousness and consequences of the vulnerabilities.

- Proof of existence of vulnerability.

Identified Version

- 7.4.10

Latest Version

- 7.4.33 (in this branch)

Vulnerability Database

```

- **Solutions to the above-mentioned vulnerability (Remedy).**

1. Regular PHP upgrades to the most recent stable release or a supported version that receives security updates and fixes are essential to reducing these risks. This makes sure that your web application takes advantage of the most recent PHP development team features, performance upgrades, and security patches.
2. Applying patches created by the PHP community to address the specific vulnerabilities you've found can be an option if updating to the most recent version of PHP is not possible right away. The known security flaws in the out-of-date version may be fixed by these patches.
3. You can further defend your application against potential vulnerabilities by adhering to best practices in web application security, such as input validation, safe coding techniques, and frequent security audits.
4. To enforce security settings, review and alter the php.ini configuration file. Disable, for instance, elements of your program that are known to be weak points or superfluous. To assist in locating potential security concerns, enable proper error reporting.
5. To add an additional layer of defense against typical web vulnerabilities, use a web application firewall. WAFs can aid in the detection and mitigation of attacks utilizing known exploits that target PHP vulnerabilities.

2. Sensitive data exposure.

i. RSA private key compromised.

RSA Private Key Detected GET

<https://curl.se/dash/tests/stunnel.pem>

MEDIUM

Under this OWASP category I have identified vulnerabilities sensitive data exposure that can occur due to bad implementation security under domain of <https://curl.se/dash/tests/stunnel.pem>

When attempting to connect onto a secure server, the client application uses a digital signature to demonstrate that you own the private key. The server then verifies that the signature is valid and that the public key is approved for your username. If everything is okay, access is allowed to you. If this key is compromised, then there is no point in using the secure mechanism. Anyone can access your secure server with this key.

- **Impacts of using compromised RSA key to server authentication.**

When the private key is not password-protected, anyone who obtains it can access all your accounts.

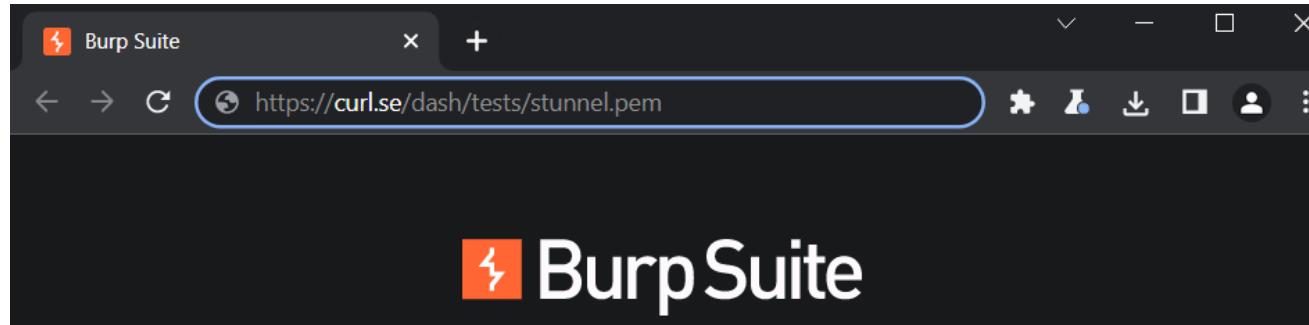

1. Even if it is password-protected, an attacker with average computational power can test a vast variety of password combinations. Your passphrase can probably be cracked in a matter of seconds if it contains a dictionary word.
2. The attacker may be able to impersonate authorized users, obtain access to user accounts without authorization, or fake digital signatures if the leaked RSA key is used for user authentication or digital signatures. As a result, users may perform unlawful activities on their behalf, such as takeover of accounts, data manipulation, or fraudulent transactions.
3. In SSL/TLS certificates, RSA keys are frequently used to provide secure communication between clients and your web server. An attacker may be able to decrypt and intercept sensitive data sent via HTTPS connections if the RSA key is compromised. As a result, user conversations are no longer secure or private, leaving critical information vulnerable to interceptions or man-in-the-middle assaults.
4. An attacker may edit the application code, introduce malicious code, or disseminate modified copies of your application if the compromised RSA key is utilized for code signing or application integrity checks. This jeopardizes the reliability and integrity of your program and may cause the spread of malware or unauthorized changes.

Because of this vulnerability marked as **medium** It's a must to address it with a good solution.

- **Step to reproduce this vulnerability.**

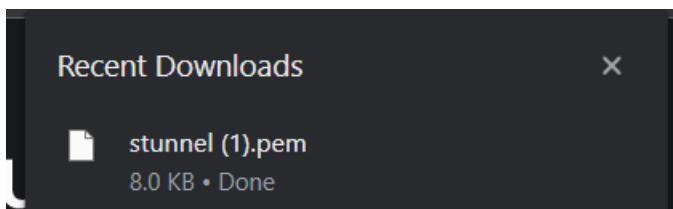

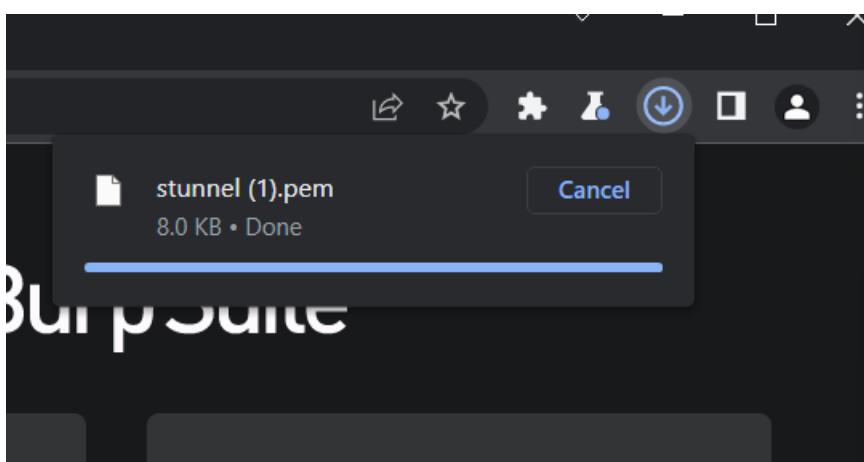

1. Find the web application endpoint or feature that is causing the RSA secret key to appear in the response body.
2. To intercept and inspect HTTP requests and replies, set up a web proxy tool like Burp Suite or OWASP ZAP.
3. Set up your web browser to use the web proxy. The traffic between your browser and the web application can then be recorded and analyzed thanks to this.
4. Use the proxy tool to start recording HTTP traffic, then send a request that results in a response that contains the RSA secret key. This could entail submitting a form, using an API, or carrying out a certain task inside of your program.
5. Examine the response in the proxy tool after the request has been captured. Check the response body for the RSA secret key or any other private information that shouldn't be shared.
6. To ensure that the RSA secret key is consistently disclosed in the response body, test various scenarios or inputs.

- **Proof of concept.**

- **Solutions to the above-mentioned vulnerability (Remedy).**

1. The first and most important step is to delete the RSA private key from the web application's response. Check that no server response, including HTTP response bodies, headers, or any other network transmission, contains the private key.
2. Instead of including the private key in the response from the web application, securely store it on the server or in a separate key management system. To ensure that only authorized individuals can access and handle the private key, implement the necessary access controls.
3. Use secure communication channels, Make that the web application encrypts data while it is being transmitted between the server and the client via a secure communication channel, such as HTTPS/TLS. This provides defense against listening devices and man-in-the-middle attacks.
4. Follow standard practices for key management, such as routinely updating and rotating the private key, limiting access to only authorized users, and implementing safe backup and recovery methods. To safely manage and store the private key, think about utilizing a hardware security module (HSM).

5. Challenges faced & how did I overcome them.

Challenge 1: Identifying Targets and Scope

- Initially, it was challenging to select the right targets and understand the scope of the bug bounty program.
- To overcome this, I extensively researched and studied the program guidelines, scoping documents, and any available information about the target organization.
- I also utilized tools like recon-ng, subdomain enumeration, and Google dorking to identify potential targets within the program's scope.

Challenge 2: Prioritizing Vulnerabilities

- With numerous potential vulnerabilities to explore, it was difficult to prioritize and focus on the most critical ones.
- To overcome this challenge, I adopted a risk-based approach. I analyzed the potential impact and exploitability of each vulnerability, considering factors like data sensitivity, user privacy, and the organization's overall security posture.
- I prioritized vulnerabilities with high impact, easy exploitability, and a larger attack surface.

Challenge 3: Evading Security Controls

- Many organizations implement security controls like WAFs, rate limiting, and IP blocking, which can hinder the discovery of vulnerabilities.
- To overcome this challenge, I employed various techniques such as bypassing WAFs using different encodings or payloads, evading rate limits by rotating IPs or using multi-threading and employing anti-detection techniques to bypass IP blocking.
- Continuous monitoring and analyzing the target's response allowed me to adapt my techniques and avoid detection.

Challenge 4: Dealing with False Positives

- Identifying false positives was a common challenge, as not every reported vulnerability turned out to be genuine.
- To address this, I ensured thorough testing and validation of potential vulnerabilities before reporting them. I followed a systematic methodology, attempting to reproduce the issue multiple times to rule out false positives.
- By gathering sufficient evidence and providing a detailed explanation in my reports, I minimized the chances of false positives and increased the chances of successful vulnerability identification.

Challenge 5: Collaborating with Program Owners

- Communication and collaboration with program owners can sometimes be challenging, especially when clarifying the impact or receiving feedback on reported vulnerabilities.
- To overcome this, I maintained clear and concise communication with the program owners. I provided detailed reports, including proof-of-concepts, screenshots, and steps to reproduce the vulnerabilities.
- If there were any communication barriers or delays, I remained patient and persistent, following up with program owners until we were on the same page.

Challenge 6: Staying Motivated

- Bug bounty programs can be mentally challenging, particularly when encountering long periods without discovering significant vulnerabilities or facing repeated rejections.
- To stay motivated, I set realistic goals and milestones, celebrating smaller successes along the way. I actively engaged in bug bounty communities, seeking advice, and learning from others' experiences.
- I also maintained a growth mindset, recognizing that each attempt was an opportunity to learn and improve my skills, regardless of the outcome.

6. Reflections & takeaways.

1. Real-world Exposure:

- Participating in a bug bounty program provided me with valuable real-world exposure to various technologies, systems, and applications, allowing me to understand their security vulnerabilities in practical scenarios.

2. Hands-on Experience:

- Through the bug bounty program, I gained hands-on experience in identifying, exploiting, and reporting vulnerabilities, strengthening my technical skills and knowledge in cybersecurity.

3. Expanded Knowledge:

- The bug bounty program expanded my knowledge across different domains of cybersecurity, including web application security, network security, mobile security, and more. I gained insights into new attack vectors, vulnerabilities, and mitigation techniques.

4. Improved Analytical Skills:

- Engaging in bug bounty programs enhanced my analytical skills, as I learned to dissect complex systems, trace attack paths, and identify potential security weaknesses. This analytical mindset carries over to other areas of my work.

5. Effective Communication:

- Participating in the bug bounty program improved my communication skills, as I learned to document and explain vulnerabilities clearly and concisely in my reports. This skill is crucial for effective collaboration with program owners and other security professionals.

6. Collaboration and Networking:

- Bug bounty programs fostered collaboration and networking opportunities with fellow security researchers and program owners. Through engagement in bug bounty communities, I have learned from others' experiences, shared knowledge, and built professional connections.

Conclusion.

In conclusion, my bug bounty journey has been an incredibly enriching experience that has allowed me to dive deep into the world of cybersecurity. Through this report, I have shared my findings, challenges, and reflections, showcasing the growth and knowledge I have gained throughout my bug bounty activities [30].

Participating in bug bounty programs has not only honed my technical skills but also fostered critical thinking, problem-solving, and effective communication. I have encountered various vulnerabilities, ranging from common misconfigurations to complex logic flaws, and have successfully reported them to program owners, contributing to the overall security of their systems.

Looking back at my bug bounty journey, I am filled with a sense of pride and satisfaction. The experience has expanded my knowledge, broadened my network within the cybersecurity community, and provided a platform for continuous learning and improvement. I am grateful for the opportunities bug bounty programs have presented and for the individuals who have supported me along the way [31].

As I conclude this bug bounty report, I am excited to continue my journey as a cybersecurity student, further refining my skills, staying updated with emerging threats, and making a positive impact in securing digital systems. Bug bounty programs have not only served as a means of personal growth but have also reinforced my passion for protecting organizations and individuals from malicious actors.
